#### Abstract

This note describes a search for direct stop quark pair production in the single lepton channel using 9.7 fb<sup>-1</sup> of pp collision data at  $\sqrt{s} = 8$  TeV taken with the CMS detector in 2012. A search for an excess of events over the Standard Model prediction is performed in a sample with a single isolated electron or muon, several jets including a b-tagged jet, missing transverse energy, and large transverse mass.

# 1 Introduction

30

- This note presents a search for the production of supersymmetric (SUSY) stop quark pairs in events with a single isolated lepton, several jets, missing transverse energy, and large transverse mass. We use a data sample corresponding to an integrated luminosity of 9.7 fb<sup>-1</sup>. This search is of theoretical interest because of the critical role played by the stop quark in solving the hierarchy problem in SUSY models. This solution requires that the stop quark be light, less than a few hundred GeV and hence within reach for direct pair production. We focus on two decay modes  $\tilde{t} \to t\chi_1^0$  and  $\tilde{t} \to b\chi_1^+$  which are expected to have large branching fractions if they are kinematically accessible, leading to:
- 9  $pp \to \tilde{t}\bar{\tilde{t}} \to t\bar{t}\chi_1^0\chi_1^0$ , and •  $pp \to \tilde{t}\bar{\tilde{t}} \to b\bar{b}\chi_1^+\chi_1^- \to b\bar{b}W^+W^-\chi_1^0\chi_1^0$ .
- Both of these signatures contain high transverse momentum  $(p_T)$  jets including two b-jets, and missing transverse energy  $(E_{\rm T}^{\rm miss})$  due to the invisible  $\chi_1^0$  lightest SUSY particles (LSP's). In addition, the presence 12 of two W bosons leads to a large branching fraction to the single lepton final state. Hence we require 13 the presence of exactly one isolated, high  $p_{\rm T}$  electron or muon, which provides significant suppression of several backgrounds that are present in the all-hadronic channel. The largest backgrounds for this 15 signature are semi-leptonic  $t\bar{t}$  and W+jets. These backgrounds contain a single leptonically-decaying W boson, and the transverse mass  $(M_T)$  of the lepton-neutrino system has a kinematic endpoint requiring 17  $M_{\rm T} < M_{\rm W}$ . For signal stop quark events, the presence of additional LSP's in the final states allows the  $M_{\rm T}$  to exceed  $M_{\rm W}$ . Hence we search for an excess of events with large  $M_{\rm T}$ . The dominant background 19 in this kinematic region is dilepton tt where one of the leptons is not identified, since the presence of two neutrinos from leptonically-decaying W bosons allows the  $M_{\rm T}$  to exceed  $M_{\rm W}$ . Backgrounds are 21 estimated from Monte Carlo (MC) simulation, with careful validation and determination of scale factors 22 (where necessary) and corresponding uncertainties based on data control samples. 23

The expected stop quark pair production cross section (see Fig. 1) varies between 18 pb for  $m_{\tilde{t}} = 200 \text{ GeV}$  and 0.09 pb for  $m_{\tilde{t}} = 500 \text{ GeV}$  [1]. The critical challenge of this analysis is due to the fact that for light stop quarks ( $m_{\tilde{t}} \approx m_t$ ), the production cross section is large but the kinematic distributions, in particular  $M_{\rm T}$ , are very similar to SM t $\bar{t}$  production. In this regime it becomes very difficult to distinguish the signal and background. For large stop quark mass the kinematic distributions differ from those in SM t $\bar{t}$  production, but the cross section decreases rapidly, reducing the signal-to-background ratio.

# 2 Overview and Strategy for Background Determination

We are searching for a  $t\bar{t}\chi^0\chi^0$  or  $WbW\bar{b}\chi^0\chi^0$  final state (after top decay in the first mode, the final states are actually the same). So to first order this is " $t\bar{t}+$  extra  $E_{\rm T}^{\rm miss}$ ".

We work in the  $\ell$ + jets final state, where the main background is  $t\bar{t}$ . We look for  $E_{\rm T}^{\rm miss}$  inconsistent with  $W \to \ell \nu$ . We do this by concentrating on the  $\ell \nu$  transverse mass  $(M_T)$ , since except for resolution and W-off-shell effects,  $M_T < M_W$  for  $W \to \ell \nu$ . Thus, the initial analysis is simply a counting experiment in the tail of the  $M_T$  distribution.

The event selection is one-and-only-one high  $p_{\rm T}$  isolated lepton, four or more jets, and an  $E_{\rm T}^{\rm miss}$  cut. At least one of the jets has to be b tagged to reduce W+ jets. The event sample is then dominated by  $t\bar{t}$ , but there are also contributions from W+ jets, single top, dibosons, as well as rare SM processes such as tW.

The  $t\bar{t}$  events in the  $M_T$  tail can be broken up into two categories: (i)  $t\bar{t} \to \ell + j$  ets, and (ii)  $t\bar{t} \to \ell^+ \ell^-$  where one of the two leptons is not found by the second-lepton-veto (here the second lepton can be a hadronically decaying  $\tau$ ). For a reasonable  $M_T$  cut, say  $M_T > 150$  GeV, the dilepton background is approximately 70% of the total. This is because in dileptons there are two neutrinos from W decay, thus  $M_T$  is not bounded by  $M_W$ . This is a very important point: while it is true that we are looking in the tail of  $M_T$ , the bulk of the background events end up there not because of some exotic  $E_T^{\rm miss}$  reconstruction failure, but because of well understood physics processes. This means that the background estimate can be taken from Monte Carlo (MC) after carefully accounting for possible data/MC differences.

The search is performed in a number of Signal Regions (SRs) defined by minimum requirements on  $E_{\rm T}^{\rm miss}$  and  $M_T$ . The SRs are defined in Section 4.3.

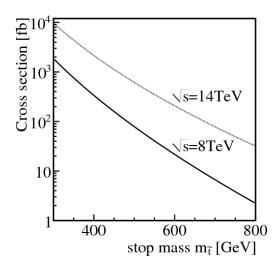

Figure 1: The stop quark pair production cross section as a function of the stop quark mass [2].

In Section 5 we will describe the analysis of various Control Regions (CRs) that are used to test the Monte Carlo model and, if necessary, to extract data/MC scale factors. In this section we give a general description of the procedure. The details of how the final background prediction is assembled are given in Section 8.

One general point is that in order to minimize systematic uncertainties, the MC background predictions are whenever possible normalized to the bulk of the  $t\bar{t}$  data, i.e. events passing all of the requirements but with  $M_T \approx 80$  GeV. This (mostly) removes uncertainties due to  $\sigma(t\bar{t})$ , lepton ID, trigger efficiency, luminosity, etc.

### 2.1 $\ell$ + jets background

59

The  $\ell+$  jets background is dominated by  $t\bar{t} \to \ell+$  jets, but also includes some W+ jets as well as single top. The MC input used in the background estimation is the ratio of the number of events with  $M_T$  in the signal region to the number of events with  $M_T \approx 80$  GeV. This ratio is (possibly) corrected by a data/MC scale factor obtained from a study of CRs, as outlined below.

Note that the ratio described above is actually different for  $t\bar{t}/{\rm single}$  top and W+ jets. This is because in W events there is a significant contribution to the  $M_T$  tail from very off-shell Ws. This contribution is much smaller in top events because  $M(\ell\nu)$  cannot exceed  $M_{top}-M_b$ . Therefore the large  $M_T$  tail in  $t\bar{t}/{\rm single}$  top is dominated by jet resolution effects, while for  $W+{\rm jets}$  events the large  $M_T$  tail is dominated by off-shell W production.

For W+ jets the ability of the Monte Carlo to model this ratio  $(R_{wjet})$  is validated in a sample of  $\ell+$  jets enriched in W+ jets by the application of a b-veto. The equivalent ratio for top events  $(R_{top})$  is tested in a sample of well identified  $Z \to \ell\ell$  with one lepton added to the  $E_{\rm T}^{\rm miss}$  calculation. This sample is well suited to testing the resolution effects on the  $M_T$  tail, since off-shell effects are eliminated by the Z-mass requirement. However, this test is unfortunately statistically limited and its usefulness is limited to event

- selections with modest  $E_{
  m T}^{
  m miss}$  requirements.
- Note that the fact that the ratios are different for  $t\bar{t}/\mathrm{single}$  top and W+ jets introduces a systematic
- uncertainty in the background calculation because one needs to know the relative fractions of these two
- components in the  $M_T \approx 80 \text{ GeV lepton} + \text{jets sample}$ .

# 78 2.2 Dilepton background

- To suppress dilepton backgrounds, we veto events with an isolated track of  $p_T > 10$  GeV (see Sec. 4.2
- for details). Being the common feature for electron, muon, and one-prong tau decays, this veto is highly
- efficient for rejecting  $t\bar{t}$  to dilepton events. The remaining dilepton background can be classified into the
- 82 following categories:
- lepton is out of acceptance  $(|\eta| > 2.5)$ 
  - lepton has  $p_{\rm T} < 10$  GeV, and is inside the acceptance
- lepton has  $p_{\rm T} > 10$  GeV, is inside the acceptance, but survives the additional isolated track veto
- The last category includes 1-prong and 3-prong hadronic tau decays, as well as electrons and muons either
- from direct W decay or via  $W \to \tau \to \ell$  decay that fail the isolation requirement. We note that at present
- we do not attempt to veto 3-prong tau decays as they are about 15% of the total dilepton background
- 89 according to the MC.
- The high  $M_T$  dilepton background predictions come from MC, but their rate is normalized to the  $M_T \approx 80$
- $_{91}$  GeV peak. In order to perform this normalization in data, the rare background events in the  $M_T$  peak
- <sup>92</sup> are subtracted off. This also introduces a systematic uncertainty.
- There are two types of effects that can influence the MC dilepton prediction: physics effects and instru-
- mental effects. We discuss these next, starting from physics.
- First of all, many of our  $t\bar{t}$  MC samples (e.g. MadGraph) have BR( $W \to \ell\nu$ ) =  $\frac{1}{9}$  = 0.1111. PDG says
- $BR(W \to \ell \nu) = 0.1080 \pm 0.0009$ . This difference matters, so the  $t\bar{t}$  MC must be corrected to account for
- 97 this

115

- Second, our selection is  $\ell + 4$  or more jets. A dilepton event passes the selection only if there are two
- 99 additional jets from ISR, or one jet from ISR and one jet which is reconstructed from the unidentified
- lepton, e.g., a three-prong tau. Therefore, all MC dilepton  $t\bar{t}$  samples used in the analysis must have
- their jet multiplicity corrected (if necessary) to agree with what is seen in  $t\bar{t}$  data. We use a data control
- sample of well identified dilepton events with  $E_{\mathrm{T}}^{\mathrm{miss}}$  and at least one jet (including at least one b-tag) as
- 103 a template to "adjust" the  $N_{iet}$  distribution of the  $t\bar{t} \to \text{dileptons MC}$  samples.
- The final physics effect has to do with the modeling of  $t\bar{t}$  production and decay. Different MC models
- could in principle result in different BG predictions. Therefore we use several different  $t\bar{t}$  MC samples
- using different generators and different parameters, to test the stability of the dilepton BG prediction.
- All these predictions, after corrections for branching ratio and  $N_{jet}$  dependence, are compared to each
- other. The spread is a measure of the systematic uncertainty associated with the  $t\bar{t}$  generator modeling.
- 109 The main instrumental effect is associated with the efficiency of the isolated track veto. We use tag-
- and-probe to compare the isolated track veto performance in Z + 4 jets data and MC. Note that the
- performance of the isolated track veto is not exactly the same on  $e/\mu$  and on one prong hadronic tau
- decays. This is because the pions from one-prong taus are often accompanied by  $\pi^0$ 's that can then
- result in extra tracks due to photon conversions. We let the simulation take care of that. Note that JES
- uncertainties are effectively "calibrated away" by the  $N_{jet}$  rescaling described above.

# 2.3 Other backgrounds

- Other backgrounds are tW, ttV, dibosons, tribosons, and Drell Yan. These are small. They are taken from MC with appropriate scale factors for trigger efficiency, and reweighting to match the distribution
- of reconstructed primary vertices in data.

# 119 2.4 Future improvements

121

122

123

124

125

127

130

131

132

134

Finally, there are possible improvements to this basic analysis strategy that can be added in the future:

- Move from counting experiment to shape analysis. But first, we need to get the counting experiment under control.
  - Add an explicit three prong tau veto
  - Do something to require that three of the jets in the event be consistent with  $t \to Wb, W \to q\bar{q}$ . This could help reject some of the dilepton BG in the search for  $\tilde{t} \to t\chi^0$ , but is not applicable to the  $\tilde{t} \to b\chi^+$  search.
    - Consider the  $M(\ell b)$  variable, which is not bounded by  $M_{top}$  in  $\widetilde{t} \to b\chi^+$

# 3 Data Samples

The datasets used for this analysis are summarized in Tables 1 (data) and 2 (MC). The total integrated luminosity is  $9.7 \text{ fb}^{-1}$  after applying the official good run list. The main  $t\bar{t}$  Monte Carlo sample is generated with Powheg since this sample has the largest number of events, though samples with alternative generators such as Madgraph are also used for the derivation of systematic uncertainties in the  $t\bar{t}$  background prediction. The triggers used to select both the signal and control samples are also summarized in Table 3.

Here we define the selections of leptons, jets, and  $E_{\rm T}^{\rm miss}$ . We also describe our measurements of the lepton and trigger efficiency. The analysis uses several different Control Regions (CRs) in addition to the Signal Regions (SRs). All of these different regions are defined in this section. This section also includes some information on the basic MC corrections that we apply.

# 4.1 Single Lepton Selection

The single lepton selection is based on the following criteria, starting from the requirements described on https://twiki.cern.ch/twiki/bin/viewauth/CMS/SUSYstop#SINGLE\_LEPTON\_CHANNEL (revision r20)

- satisfy the trigger requirement (see Table 3). Note that the analysis triggers are inclusive single lepton triggers. Dilepton triggers are used only for the dilepton control region.
- select events with one high  $p_{\rm T}$  electron or muon, requiring
  - $-p_{\rm T} > 30~{\rm GeV}/c$  and  $|\eta| < 1.4442(2.1)$  for electrons (muons). The restriction to the barrel for electrons is motivated by an observed excess of events with large  $M_{\rm T}$  with endcap electrons in the b-veto control region, and does not significantly reduce the signal acceptance since the leptons tend to be central.
  - muon ID criteria is based on the 2012 POG recommended tight working point
  - electron ID critera is based on the 2012 POG recommended medium working point
  - PF-based isolation ( $\Delta R < 0.3$ ) relative isolation < 0.15 and absolute isolation < 5 GeV. PU corrections are performed with the  $\Delta \beta$  scheme for muons and effective-area fastjet rho scheme for electrons (as recommended by the relevant POGs).
  - $-|p_{\mathrm{T}}(\mathrm{PF}_{\mathrm{lep}}) p_{\mathrm{T}}(\mathrm{RECO}_{\mathrm{lep}})| < 10 \text{ GeV}$
  - $-E/p_{\rm in} < 4$  (electrons only)
  - We remove electron events with  $E_{\rm T}^{\rm miss} > 50$  GeV and  $M_T > 100$  GeV with at least one crystal in the supercluster with laser correction > 2.1
- require at least 4 PF jets in the event with  $p_T > 30$  GeV within  $|\eta| < 2.5$  out of which at least 1 satisfies the CSV medium working point b-tagging requirement
- require moderate  $E_{\rm T}^{\rm miss} > 50$  GeV (type1-corrected pfmet with  $\phi$  corrections applied as described in Sec. 4.7.1).
- Isolated track veto, see Section 4.2

#### 4.2 Isolated track veto

The isolated track veto is intended to remove top dilepton events. Looking for an isolated track is an effective way of identifying  $W \to e$ ,  $W \to \mu$ ,  $W \to \tau \to \ell$ , and  $W \to \tau \to h^{\pm} + n\pi^{0}$ . The requirements on the track are

- $P_T > 10 \text{ GeV}$
- Relative track isolation < 10% computed from charged PF candidates with  $d_Z < 0.05$  cm from the primary vertex.

#### 4.3 Signal Region Selection

The signal regions (SRs) are selected to improve the sensitivity for the single lepton requirements and cover a range of scalar top scenarios. The  $M_{\rm T}$  and  $E_{\rm T}^{\rm miss}$  variables are used to define the signal regions and the requirements are listed in Table 4.

<sup>1)</sup> This is an ad-hoc removal based on run-event numbers, since the problem was found very recently and the filter was not available when we processed the events.

Signal Region	Minimum $M_{\rm T}$ [GeV]	Minimum $E_{\mathrm{T}}^{\mathrm{miss}}$ [GeV]
SRA	150	100
SRB	120	150
$\operatorname{SRC}$	120	200
$\operatorname{SRD}$	120	250
SRE	120	300
$\operatorname{SRF}$	120	350
SRG	120	400

Table 4: Signal region definitions based on  $M_{\rm T}$  and  $E_{\rm T}^{\rm miss}$  requirements. These requirements are applied in addition to the baseline single lepton selection.

Table 5 shows the expected number of SM background yields for the SRs. A few stop signal yields for four values of the parameters are also shown for comparison. The signal regions with looser requirements are sensitive to lower stop masses  $M(\tilde{t})$ , while those with tighter requirements are more sensitive to higher  $M(\tilde{t})$ .

Sample	SRA	SRB	SRC	SRD	SRE	SRF	SRG
$t\bar{t}  o \ell\ell$	$619 \pm 9$	$366 \pm 7$	$127 \pm 4$	$44 \pm 2$	$17 \pm 1$	$7\pm1$	$4\pm1$

Table 5: Expected SM background contributions and signal yields for a few sample points, including both muon and electron channels. This is "dead reckoning" MC with no correction. It is meant only as a general guide. The uncertainties are statistical only. The signal yield expected upper limits are also shown for two values of the total background systematic uncertainty, indicated in parentheses.

# 4.4 Control Region Selection

180

181

183

Control regions (CRs) are used to validate the background estimation procedure and derive systematic uncertainties for some contributions. The CRs are selected to have similar kinematics to the SRs, but have a different requirement in terms of number of b-tags and number of leptons, thus enhancing them in different SM contributions. The four CRs used in this analysis are summarized in Table 6.

Selection Criteria	exactly 1 lepton	exactly 2 leptons	1 lepton + isolated track
0 b-tags	CR1) W+Jets dominated: Validate W+Jets $M_{\rm T}$ tail	CR2) apply Z-mass constraint $\rightarrow$ Z+Jets dominated: Validate $t\bar{t} \rightarrow \ell + \text{jets } M_{\text{T}}$ tail comparing data vs. MC "pseudo- $M_{\text{T}}$ "	CR3) not used
$\geq 1$ b-tags	SIGNAL REGION	CR4) Apply Z-mass veto $\rightarrow$ t $\bar{t} \rightarrow \ell\ell$ dominated: Validate "physics" modelling of t $\bar{t} \rightarrow \ell\ell$	CR5) $t\bar{t} \to \ell\ell$ , $t\bar{t} \to \ell\tau$ and $t\bar{t} \to \ell$ fake dominated: Validate $\tau$ and fake lepton modeling/ detector effects in $t\bar{t} \to \ell\ell$

Table 6: Summary of signal and control regions.

# 4.5 Definition of $M_T$ peak region

This region is defined as  $50 < M_T < 80 \text{ GeV}$ .

# $_{87}$ 4.6 Default ${ m tar t}$ MC sample

Our default tt MC sample is Powheg.

# 189 4.7 MC Corrections

All MC samples are corrected for trigger efficiency. In the case of single lepton selections, we apply the  $p_{\rm T}$  and  $\eta$ -dependent scale factors that we measure ourselves, see Section 4.9. In the case of dilepton selections that require the dilepton triggers, we apply overall scale factors of 0.95, 0.88, and 0.92 for ee,  $\mu\mu$ , and  $e\mu$  respectively [3].

The leptonic branching fraction used in some of the  $t\bar{t}$  MC samples differs from the value listed in the PDG  $(10.80 \pm 0.09)\%$ . Table 7 summarizes the branching fractions used in the generation of the various  $t\bar{t}$  MC samples. For  $t\bar{t}$  samples with the incorrect leptonic branching fraction, event weights are applied based on the number of true leptons and the ratio of the corrected and incorrect branching fractions.

tt Sample - Event Generator	Leptonic Branching Fraction
Madgraph	0.111
MC@NLO	0.111
Pythia	0.108
Powheg	0.108

Table 7: Leptonic branching fractions for the various  $t\bar{t}$  samples used in the analysis. The  $t\bar{t}$  MC samples produced with Madgraph and MC@NLO has a branching fraction that is almost 3% higher than the PDG value.

All tt dilepton samples are corrected (when needed and appropriate) in order to have the correct jet multiplicity distribution. This correction procedure is described in Section 5.3.1.

# $_{200}$ 4.7.1 Corrections to Jets and $E_{ m T}^{ m miss}$

The official recommendations from the Jet/MET group are used for the data and MC samples. In particular, the jet energy corrections (JEC) are updated using the official recipe. L1FastL2L3Residual (L1FastL2L3) corrections are applied for data (MC), based on the global tags GR\_R\_52\_V9 (START52\_V9B) for data (MC). In addition, these jet energy corrections are propagated to the  $E_{\rm T}^{\rm miss}$  calculation, following the official prescription for deriving the Type I corrections.

Events with anomalous "rho" pile-up corrections are excluded from the sample since these can correspond to events with unphysically large  $E_{\rm T}^{\rm miss}$  and  $M_{\rm T}$ . In addition, the recommended MET filters are applied. A correction to remove the  $\phi$  modulation in  $E_{\rm T}^{\rm miss}$  is also applied to the data.

#### 4.8 Lepton Selection Efficiency Measurements

In this section we measure the identification and isolation efficiencies for muons and electrons in data and MC using tag-and-probe studies. The tag is required to pass the full offline analysis selection and have  $p_{\rm T}>30$  GeV,  $|\eta|<2.1$ , and be matched to the single lepton trigger, HLT\_IsoMu24(\_eta2p1) for muons and HLT\_Ele27\_WP80 for electrons. The probe is required to have  $|\eta|<2.1$  and  $p_{\rm T}>20$  GeV. To measure the identification efficiency we require the probe to pass the isolation requirement, to measure the isolation efficiency we require the probe to pass the identification requirement.

The tag-probe pair is required to have opposite-sign and an invariant mass in the range 76–106 GeV.

In order to suppress lepton pairs from sources other than Z boson decays, we require the event to have  $E_{\rm T}^{\rm miss} < 30$  GeV and no b-tagged jets (CSV loose working point).

The muon efficiencies are summarized in Table 8 for inclusive events (i.e. no jet requirements). These efficiencies are displayed in Fig. 2 for several different jet multiplicity requirements. We currently observe

good agreement for muons with  $p_T$  up to about 300 GeV. For high  $p_T$  muons we observe a source of 221 background in the data with large impact parameters, which we suppress by requiring muon  $d_0 < 0.02$  cm 222 and  $d_Z < 0.5$  cm. The electron efficiencies are summarized in Table 9 for inclusive events (i.e. no jet 223 requirements). These efficiencies are displayed in Fig. 3 for several different jet multiplicity requirements. 224 In general we observe good agreement between the data and MC identification and isolation efficiencies. 225 We do not correct the MC for differences in lepton efficiency. In the background calculation, we do 226 not take any systematics due to lepton selection efficiency uncertainties. This is because all backgrounds 227 except the rare MC background are normalized to the  $M_T$  peak, thus the lepton identification uncertainty 228 cancels out. For the rare MC these uncertainties are negligible compared to the assumed cross-section 229 uncertainty (Section 6). 230

Table 8: Summary of the data and MC muon identification and isolation efficiencies measured with tag-and-probe studies.

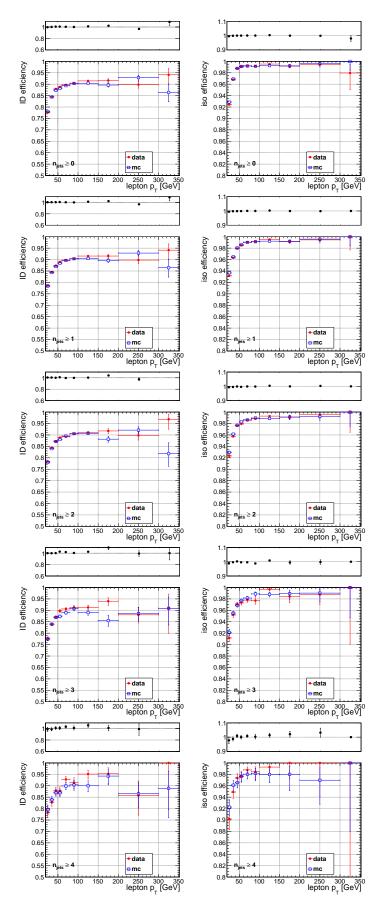

Figure 3: Comparison of the electron identification and isolation efficiencies in data and MC for various jet multiplicity requirements.

# 4.9 Trigger Efficiency Measurements

In this section we measure the efficiencies of the single lepton triggers, HLT\_IsoMu24(\_eta2p1) for muons and HLT\_Ele27\_WP80 for electrons, using a tag-and-probe approach. The tag is required to pass the full offline analysis selection and have  $p_{\rm T} > 30$  GeV,  $|\eta| < 2.1$ , and be matched to the single lepton trigger. The probe is also required to pass the full offline analysis selection and have  $|\eta| < 2.1$ , but the  $p_{\rm T}$  requirement is relaxed to 20 GeV in order to measure the  $p_{\rm T}$  turn-on curve. The tag-probe pair is required to have opposite-sign and an invariant mass in the range 76–106 GeV.

The measured trigger efficiencies are displayed in Fig. 4 and summarized in Table 10 (muons) and Table 11 (electrons). These trigger efficiencies are applied to the MC when used to predict data yields selected by single lepton triggers.

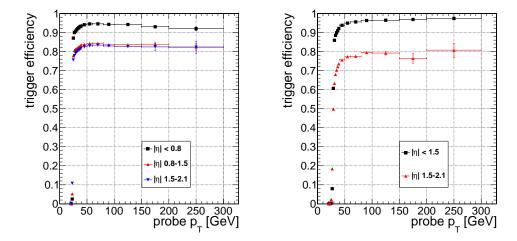

Figure 4: Efficiency for the single muon trigger HLT\_IsoMu24(\_eta2p1) (left) and single electron trigger HLT\_Ele27\_WP80 (right) as a function of lepton  $p_T$ , for several bins in lepton  $|\eta|$ .

Table 10: Summary of the single muon trigger efficiency HLT\_IsoMu24( $\_$ eta2p1). Uncertainties are statistical.

279

The CR studies described in this Section are key to validating the background predictions. The CRs are defined in Section 4.4.

CR1 and CR2 are designed to test the  $M_T$  tail in W+ jets and  $t\bar{t}$  respectively. Note that, as explained in Section 2.1, these tails are different in the two samples because the off-shell effects are much more pronounced for W+ jets (the s- and t-channel single top have the same  $M_T$  tail as  $t\bar{t}$ ). To put things in perspective, keep in mind that these backgrounds are only about 15% of the total, see Table 5.

CR4 and CR5 address the dominant  $t\bar{t}$  dilepton background. In CR4 we test the  $M_T$  tail in well identified dilepton events. In CR5 we test the same quantity, but in events where the second lepton is identified as an isolated track. Clearly CR4 and CR5 overlap.

# 5.1 W+Jets MC Modelling Validation from CR1

The estimate of the uncertainty on this background is based on CR1, defined by applying the full signal selection, including the isolated track veto, but requiring 0 b-tags (CSV medium working point as described in Sec. 4). The sample is dominanted by W+jets and is thus used to validate the MC modelling of this background.

In Table 12 we show the amount that we need to scale the W+jets MC by in order to have agreement between data and Monte Carlo in the  $M_T$  peak region, defined as  $50 < M_T < 80$  GeV, for the different signal regions. (Recall, the signal regions have different  $E_{\rm T}^{\rm miss}$  requirements). These scale factors are not terribly important, but it is reassuring that they are not too different from 1.

Sample	CR1PRESEL	CR1A	CR1B	CR1C	CR1D	CR1E	CR1F	CR1G
$\mu M_{\mathrm{T}}\text{-SF}$	$0.92 \pm 0.02$	$0.97 \pm 0.03$	$0.90 \pm 0.04$	$0.91 \pm 0.06$	$0.93 \pm 0.09$	$0.98 \pm 0.13$	$0.94 \pm 0.18$	$0.96 \pm 0.25$
e $M_{\mathrm{T}}$ -SF	$0.94 \pm 0.02$	$0.90 \pm 0.04$	$0.84 \pm 0.05$	$0.80 \pm 0.07$	$0.83 \pm 0.10$	$0.77 \pm 0.13$	$0.86 \pm 0.20$	$0.87 \pm 0.29$

Table 12:  $M_{\rm T}$  peak Data/MC scale factors applied to  $W+{\rm jets}$  samples. No scaling is made for backgrounds from other processes. CR1PRESEL refers to a sample with  $E_{\rm T}^{\rm miss} > 50$  GeV. The uncertainties are statistical only.

Next, in Fig 5, 6, and 7, we show plots of  $E_{\rm T}^{\rm miss}$  and then  $M_T$  for different  $E_{\rm T}^{\rm miss}$  requirements corresponding to those defining our signal regions. It is clear that there are more events in the  $M_T$  tail than predicted from MC. This implies that we need to rescale the MC W+jets background in the tail region.

The rescaling is explored in Table 13, where we compare the data and MC yields in the  $M_T$  signal regions and in a looser control region. Note that the MC is normalized in the  $M_T$  peak region by rescaling the W+jets component according to Table 12.

We also derive data/MC scale factors. As shown in Table 13, these are derived in two different ways, separately for muons and electrons and then combined, as follows:

- For the first three sets of scale factors, above the triple horizontal line, we calculate the scale factor as the amount by which we would need to rescale all MC (W+jets,  $t\bar{t}$ , single top, rare) in order to have data-MC agreement in the  $M_T$  tail.
- For the next three set of scale factors, below the triple horizontal line, we calculate the scale factor as the amount by which we would need to scale W+jets keeping all other components fixed in order to have data-MC agreement in the tail.

The true W+jets scale factor is somewhere in between these two extremes. We also note that there is no statistically significant difference between the electron and muon samples. We use these data to extract a data/MC scale factor for W+jets which will be used to rescale the W+jets MC tail. This scale factor is listed in the last line of the Table, and is called  $SFR_{wjets}$ . It is calculated as follows.

- Separately for each signal region
- As the average of the two methods described above

Table 13: Yields in  $M_{\rm T}$  tail comparing the MC prediction (after applying SFs) to data. CR1PRESEL refers to a sample with  $E_{\rm T}^{\rm miss} > 50$  GeV and  $M_{\rm T} > 150$  GeV. See text for details.

• Including the statistical uncertainty

280

• Adding in quadrature to the uncertainty one-half of the deviation from 1.0

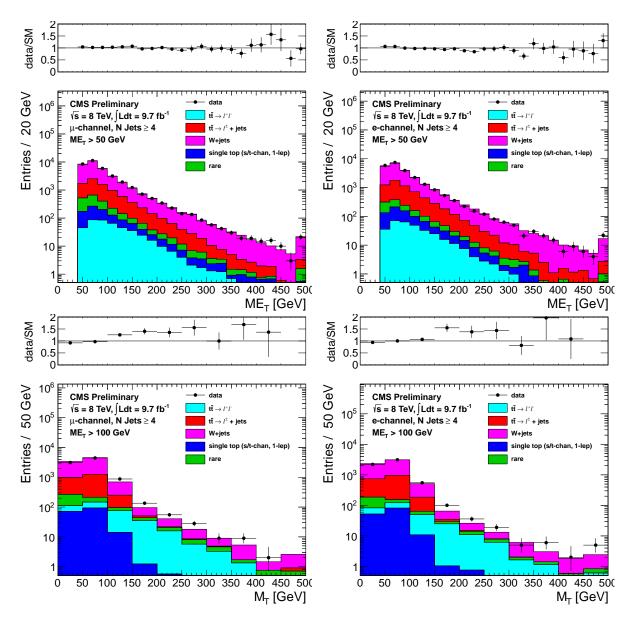

Figure 5: Comparison of the  $E_{\rm T}^{\rm miss}$  (top) and  $M_{\rm T}$  for  $E_{\rm T}^{\rm miss} > 100$  (bottom) distributions in data vs. MC for events with a leading muon (left) and leading electron (right) satisfying the requirements of CR1.

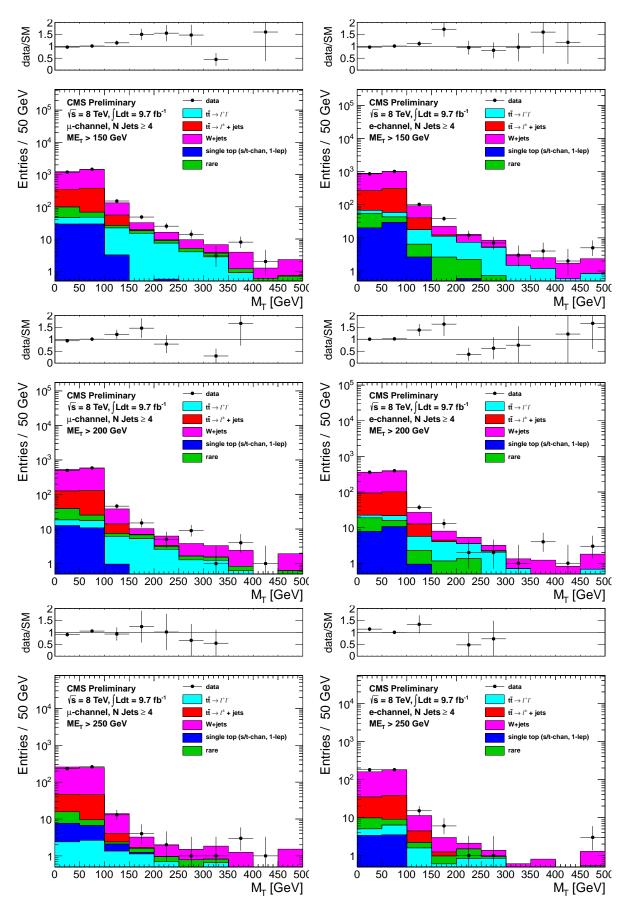

Figure 6: Comparison of the  $M_{\rm T}$  distribution in data vs. MC for events with a leading muon (left) and leading electron (right) satisfying the requirements of CR1. The  $E_{\rm T}^{\rm miss}$  requirements used are 150 GeV (top), 200 GeV (middle) and 250 GeV (bottom).

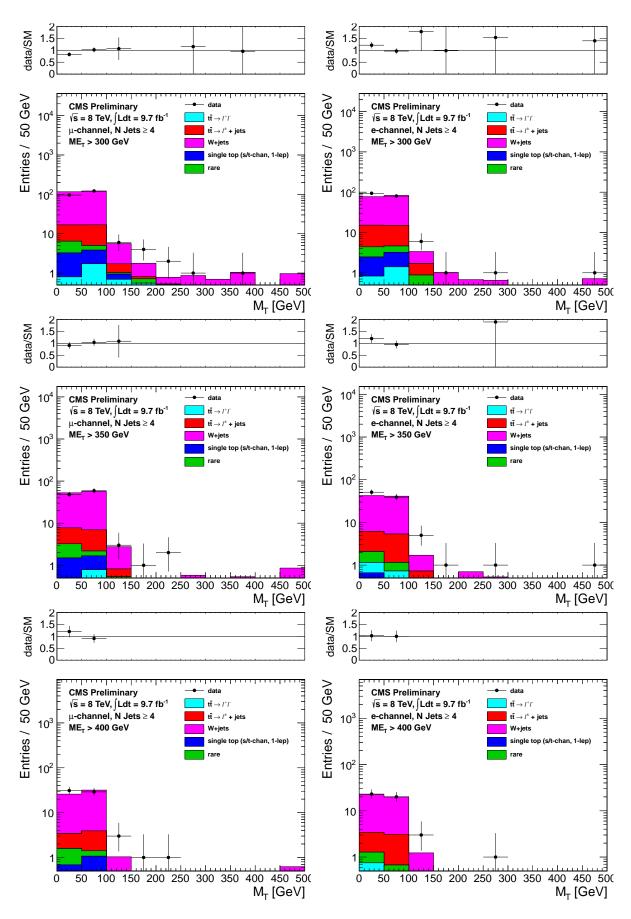

Figure 7: Comparison of the  $M_{\rm T}$  distribution in data vs. MC for events with a leading muon (left) and leading electron (right) satisfying the requirements of CR1. The  $E_{\rm T}^{\rm miss}$  requirements used are 300 GeV (top), 350 GeV (middle) and 400 GeV (bottom).

# 5.2 Single Lepton Top MC Modelling Validation from CR2

The  $M_{\rm T}$  tail for single-lepton top events (t $\bar{\rm t} \to \ell + {\rm jets}$  and single top) is dominated by jet resolution effects. The W cannot be far off-shell because  $M_{\rm W} < M_{\rm top}$ . The modeling of the  $M_{\rm T}$  tail from jet resolution effects can be studied using  $Z+{\rm jets}$  data and MC samples. However, as we will show below, this test is statistically limited and can only be performed for the  $E_{\rm T}^{\rm miss}$  requirements corresponding to SRA and SRB.

Z events are selected by requiring exactly 2 good leptons (satisfying ID and isolation requirements) and requiring the  $M_{\ell\ell}$  to be in the range 81 – 101 GeV. Events with additional isolated tracks are vetoed, as in Section 4.2. To reduce  $t\bar{t}$  backgrounds, events with a CSVM tag are removed. The positive lepton is treated as a neutrino and so is added to the MET:  $E_{\rm T}^{\rm miss} \to p_{\rm T}(\ell^+) + E_{\rm T}^{\rm miss}$ , and the  $M_{\rm T}$  is recalculated with the negative lepton:  $M_{\rm T}(\ell^-, E_{\rm T}^{\rm miss})$ . The resulting "pseudo- $M_{\rm T}$ " is dominated by jet resolution effects, since no off-shell Z production enters the sample due to the  $M_{\ell\ell}$  requirement. This section describes how well the MC predicts the tail of "pseudo- $M_{\rm T}$ ".

The underlying distributions are shown in Fig. 8. We then perform the exact same type of Data/MC comparison and analysis as described for CR1 in Section 5.1. For CR1 we collected the data/MC tail information in Table 13; the equivalent for CR2 is Table 14 (for CR2 the statistics are not sufficient to split electrons and muons). The last line of Table 14 gives the data/MC scale factors for the  $t\bar{t}$  lepton + jets  $M_T$  tail ( $SFR_{top}$ ). This is calculated in the same way as  $SFR_{wjets}$  of Table 13. Just as in CR1, there is an excess of data in the tails, as reflected in the values of  $SFR_{top}$ . There are insufficient events to derive scale factors for  $E_T^{miss} > 150$  GeV. As a result, the scale factors derived from CR2 are not used for the central prediction of the single-lepton top background. They serve as a valuable cross check of the predictions described in Section 7. The single lepton top predictions obtained for SRA and SRB using the  $SFR_{top}$  values described here are consistent with the default predictions.

Sample	CR2PRESEL0	CR2PRESEL1	CR2A	CR2B
MC	$32 \pm 2$	$28 \pm 2$	$10 \pm 1$	$10 \pm 1$

Table 14: Yields in  $M_{\rm T}$  tail comparing the Z+jets MC prediction (after applying SFs) to data without subtracting the non-Z+jets components (top table) and with subtracting the non-Z+jets components (bottom table). CR2PRESEL refers to a sample with  $E_{\rm T}^{\rm miss} > 50$  GeV and  $M_{\rm T} > 150$  GeV.

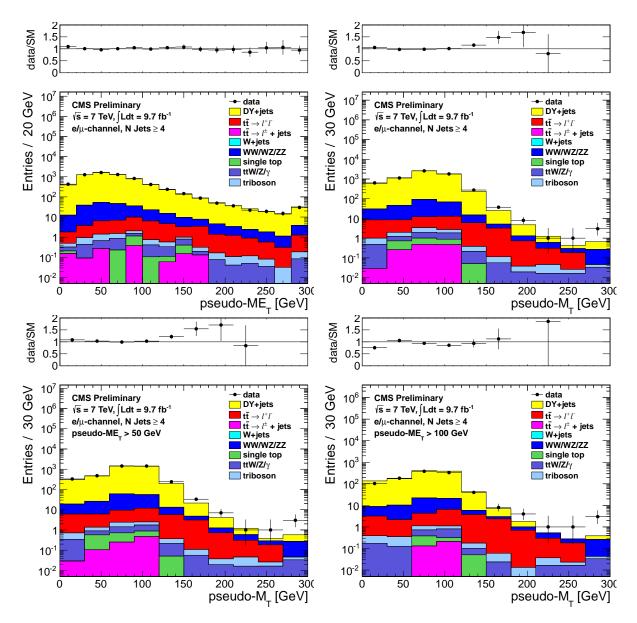

Figure 8: Comparison of the pseudo- $E_{\rm T}^{\rm miss}$  (top, left), pseudo- $M_{\rm T}$  (top, right and bottom) distributions in data vs. MC for events satisfying the requirements of CR2, combining both the muon and electron channels. The pseudo- $M_{\rm T}$  distributions are shown before any additional requirements (top, right) and after requiring pseudo- $E_{\rm T}^{\rm miss}$ >50 GeV (bottom, left) and pseudo- $E_{\rm T}^{\rm miss}$ > 100 GeV (bottom, right).

# 5.3 Dilepton studies in CR4

# 5.3.1 Modeling of Additional Hard Jets in Top Dilepton Events

Dilepton  $t\bar{t}$  events have 2 jets from the top decays, so additional jets from radiation or higher order contributions are required to enter the signal sample. In this Section we develop an algorithm to be applied to all  $t\bar{t} \to \ell\ell$  MC samples to ensure that the distribution of extra jets is properly modelled.

The modeling of additional jets in  $t\bar{t}$  events is checked in a  $t\bar{t} \to \ell\ell$  control sample, selected by requiring

- exactly 2 electrons or muons with  $p_{\rm T} > 20~{\rm GeV}$
- $E_{\rm T}^{\rm miss} > 50 {\rm ~GeV}$

305

306

313

- $\geq 1$  b-tagged jet
- Z-veto  $(|m_{\ell\ell} 91| > 15 \text{ GeV})$

Figure 9 shows a comparison of the jet multiplicity distribution in data and MC for this two-lepton control sample. After requiring at least 1 b-tagged jet, most of the events have 2 jets, as expected from the dominant process  $t\bar{t} \to \ell\ell$ . There is also a significant fraction of events with additional jets. The 3-jet sample is mainly comprised of  $t\bar{t}$  events with 1 additional emission and similarly the  $\geq$  4-jet sample contains primarily  $t\bar{t}+\geq 2$  jet events.

It should be noted that in the case of  $t\bar{t} \to \ell\ell$  events with a single reconstructed lepton, the other lepton may be mis-reconstructed as a jet. For example, a hadronic tau may be misidentified as a jet (since no tidentification is used). In this case only 1 additional jet from radiation may suffice for a  $t\bar{t} \to \ell\ell$  event to enter the signal sample. As a result, both the samples with  $t\bar{t}+1$  jet and  $t\bar{t}+2$  jets are relevant for estimating the top dilepton background in the signal region.

Table 15 shows scale factors ( $K_3$  and  $K_4$ ) used to correct the fraction of events with additional jets in MC to the observed fraction in data. These scale factors are calculated from Fig. 9 as follows:

- $N_2 = \text{data yield minus non-dilepton } t\bar{t} \text{ MC yield for } N_{\text{jets}} = 1 \text{ or } 2.$
- $N_3={
  m data}$  yield minus non-dilepton  ${
  m tar t}$  MC yield for  $N_{
  m jets}=3$
- $N_4={
  m data}$  yield minus non-dilepton  ${
  m tar t}$  MC yield for  $N_{
  m jets}\geq 4$
- $M_2 = \text{dilepton t\bar{t} MC yield for } N_{\text{jets}} = 1 \text{ or } 2$ 
  - $M_3 = \text{dilepton t\bar{t} MC yield for } N_{\text{jets}} = 3$ 
    - $M_4$  = dilepton  $t\bar{t}$  MC yield for  $N_{\rm jets} \geq 4$

333 then

331

- $SF_2 = N_2/M_2$
- $SF_3 = N_3/M_3$
- $SF_4 = N_4/M_4$
- $K_3 = SF_3/SF_2$
- $K_4 = SF_4/SF_2$

This insures that  $K_3M_3/(M_2 + K_3M_3 + K_4M_4) = N_3/(N_2 + N_3 + N_4)$  and similarly for the  $\geq 4$  jet bin.

Table 15 also shows the values of  $K_3$  and  $K_4$  for different values of the  $E_{\rm T}^{\rm miss}$  cut in the control sample definition. This demonstrates that there is no statistically significant dependence of  $K_3$  and  $K_4$  on the  $E_{\rm T}^{\rm miss}$  cut.

The factors  $K_3$  and  $K_4$  (derived with the 100 GeV  $E_{\rm T}^{\rm miss}$  cut) are applied to the  $t\bar{t} \to \ell\ell$  MC throughout the entire analysis, i.e. whenever  $t\bar{t} \to \ell\ell$  MC is used to estimate or subtract a yield or distribution.

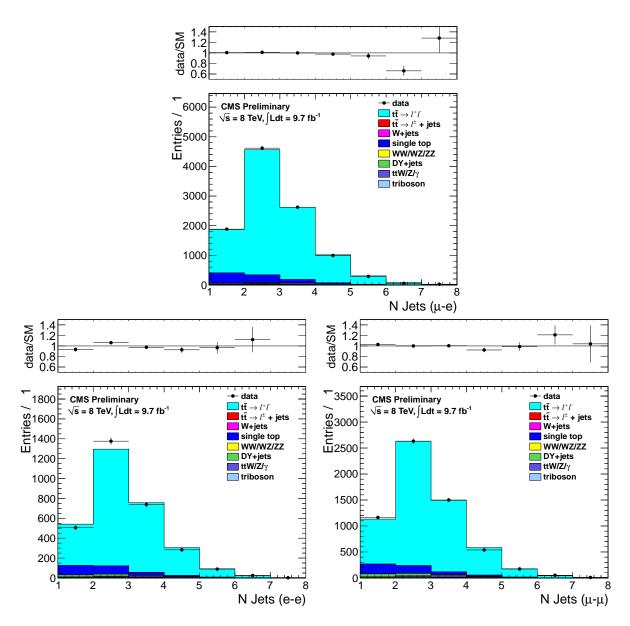

Figure 9: Comparison of the jet multiplicity distribution in data and MC for dilepton events in the e- $\mu$  (top), e-e (bottom left) and  $\mu$ - $\mu$  (bottom right) channels.

To be explicit, whenever Powheg is used, the Powheg  $K_3$  and  $K_4$  are used; whenever default MadGraph is used, the MadGraph  $K_3$  and  $K_4$  are used, etc. In order to do so, it is first necessary to count the number of additional jets from radiation and exclude leptons misidentified as jets. A jet is considered a misidentified lepton if it is matched to a generator-level second lepton with sufficient energy to satisfy the jet  $p_{\rm T}$  requirement ( $p_{\rm T} > 30$  GeV). Then  ${\rm t\bar t} \to \ell\ell$  events that need two radiation jets to enter our selection are scaled by  $K_4$ , while those that only need one radiation jet are scaled by  $K_3$ .

		$E_{ m T}^{ m miss}$ cut for data/MC scale factors									
Sample	$50 \; \mathrm{GeV}$	50 GeV 100 GeV 150 GeV 200 GeV 250 GeV 300 GeV									
N  jets = 3	$K_3 = 0.98 \pm 0.02$	$K_3 = 1.01 \pm 0.03$	$K_3 = 1.00 \pm 0.08$	$K_3 = 1.03 \pm 0.18$	$K_3 = 1.29 \pm 0.51$	$K_3 = 1.58 \pm 1.23$					
N jets $\geq 4$	$K_4 = 0.94 \pm 0.02$	$K_4 = 0.93 \pm 0.04$	$K_4 = 1.00 \pm 0.08$	$K_4 = 1.07 \pm 0.18$	$K_4 = 1.30 \pm 0.48$	$K_4 = 1.65 \pm 1.19$					

Table 15: Data/MC scale factors used to account for differences in the fraction of events with additional hard jets from radiation in  $t\bar{t} \to \ell\ell$  events. The N jets = 3 scale factor,  $K_3$ , is sensitive to  $t\bar{t}+1$  extra jet from radiation, while the N jets  $\geq$  4 scale factor,  $K_4$ , is sensitive to  $t\bar{t}+\geq$  2 extra jets from radiation. The values derived with the 100 GeV  $E_{\rm T}^{\rm miss}$  cut are applied to the  $t\bar{t} \to \ell\ell$  MC throughout the analysis.

# 5.3.2 Validation of the "Physics" Modelling of the $t\bar{t} \to \ell\ell$ MC in CR4

359

360

361

362

As mentioned above,  $t\bar{t} \to \text{dileptons}$  where one of the leptons is somehow lost constitutes the main background. The object of this test is to validate the  $M_T$  distribution of this background by looking at the  $M_T$  distribution of well identified dilepton events. We construct a transverse mass variable from the leading lepton and the  $E_T^{\text{miss}}$ . We distinguish between events with leading electrons and leading muons.

The  $t\bar{t}$  MC is corrected using the  $K_3$  and  $K_4$  factors from Section 5.3.1. It is also normalized to the total data yield separately for the  $E_{\rm T}^{\rm miss}$  requirements of the various signal regions. These normalization factors are listed in Table 16 and are close to unity.

The underlying  $E_{\rm T}^{\rm miss}$  and  $M_T$  distributions are shown in Figures 10 and 11. The data-MC agreement is quite good. Quantitatively, this is also shown in Table 17. This is a **very** important Table. It shows that for well identified  ${\rm t\bar{t}} \to \ell\ell$ , the MC can predict the  $M_T$  tail. Since the main background is also  ${\rm t\bar{t}} \to \ell\ell$  except with one "missed" lepton, this is a key test.

# 5.4 Test of control region with isolated track in CR5

363

364

366

367

368

369

This CR consists of events that pass all cuts but fail the isolated track veto cut. These events (especially in the tail of  $M_T$ ) are predominantly  $t\bar{t}$  dileptons. Thus the test in this control region is similar to that performed in CR4 and described in Section 5.3.2. There is some non-trivial complementarity because CR5 also includes events with taus and events with electrons or muons below the threshold of the CR4 selection. Also, this test is somewhat sensitive to the simulation of the track isolation requirement, since the number of dilepton events in CR5 depends on the (in)efficiency of that cut.

In CR5 there is also a significant component of  $t\bar{t} \to \ell + {\rm jets}$ , where one of the jets fluctuates to an isolated track. This component dominates at low  $M_T$  and is not necessarily well reproduced quantitatively by the simulation. This makes the normalization of the top MC a little bit tricky. We define a "pre-veto" sample as the sample of events that pass all cuts without any isolated track requirements. This sample is dominated by  $t\bar{t} \to \ell + {\rm jets}$ . We normalize the dilepton component of the top MC to that sample. This is done by normalizing the total  $t\bar{t}$  MC to the  $M_T$  peak region,  $50 < M_T < 80$  GeV in this sample.

Next we define a "post-veto" sample as the events that have an isolated track (note that we use the term "post-veto" to refer to the application of the isolated track cut of the sample, which in this case is an isolated track requirement). The  $t\bar{t} \to \ell +$  jets component is normalized in this sample, again by normalizing to the  $M_T$  peak region. These normalization factors are summarized in Table 18.

The post-veto  $t\bar{t} \to \ell\ell$  is taken from MC, but with scale factor obtained by the normalization of the "pre-veto" sample.

The underlying  $E_{\rm T}^{\rm miss}$  and  $M_T$  distributions are shown in Figures 12 and 13. The data-MC agreement is quite good. Quantitatively, this is also shown in Table 19. This is the second key test of the  $t\bar{t} \to \ell\ell$  modeling

• diboson, WW/WZ/ZZ

These backgrounds are small, contributing at the  $\sim 5\%$  level and their predictions are taken from MC, normalized to the corresponding cross sections. A 50% systematic uncertainty is assigned for all these backgrounds. Note that these backgrounds are not double-counted because the contribution to the  $M_{\rm T}$  peak region is subtracted off when deriving the  $M_{\rm T}$  peak data/MC scale factors.

Backgrounds from QCD are expected to be small in the signal regions with large  $M_{\rm T}$  and  $E_{\rm T}^{\rm miss}$ .

# 7 Tail-to-Peak ratio for lepton + jets top and W events

An important component of the background calculation is the ratio of the number of events with  $M_T$  in the signal region to the number of events with  $50 < M_T < 80$  GeV. As discussed in Section 2.1, these ratios are different for W+jets and top events.

Table 20: Ratio of MC events in the  $M_{\rm T}$ -tail over events in the  $M_{\rm T}$ -peak for  $t\bar{t} \to \ell + {\rm jets}$  (also used for 1-lepton single top) and  $W+{\rm jets}$ . These are derived before applying the b-tagging requirement.

- The MC values of these ratios are shown in Table 20. The e and  $\mu$  channel results are averaged before corrections are made.
- The MC value of  $R_{wjet}^{MC}$  is corrected based on the studies of CR1 (Section 5.1), which lead to the data/MC scale factor  $SFR_{wjet}$  (Table 13). The corrected  $R_{wjet}$  is thus given by  $R_{wjet}^{MC} \times SFR_{wjet}$ .
- There is no similar scale factor to correct the MC value of  $R_{top}^{MC}$  due to the lack of events in CR2 (Section 5.2). We must therefore use a different procedure to derive a corrected value of  $R_{top}$ .
- We start by defining optimistic (too small) and pessimistic (too large) predictions for  $R_{top}$ .
- For the pessimistic prediction, we use the W+jets MC tail-to-peak ratio and data/MC scale factor,  $R_{wjet}^{MC}$  and  $SFR_{wjet}$  (i.e. the pessimistic prediction is the same as  $R_{wjet}$ ). This prediction is too large because in W+jets events the  $M_T$  tail comes from off-shell Ws and resolution effects, while in top events to first order only resolution effects matter.
- For the optimistic prediction, we use the  $t\bar{t} \to \ell + {\rm jets}$  MC tail-to-peak ratio  $R_{top}^{MC}$ , but take the W+jets data/MC scale factor  $SFR_{wjet}$ . This prediction is too small because the true top scale factor is to first

- order the same as for on-shell Ws, while  $SFR_{wjet}$  is a weighted average of the scale factor for on-shell
- Ws (which is > 1) and the scale factor for off-shell Ws (which is close to 1 as it is well modeled by MC).
- The final prediction for  $R_{top}$  is given by the average of the optimistic and pessimistic predictions, and
- the systematic uncertainty is given by half the difference between the two.
- The corrected values of  $R_{wjet}$  and  $R_{top}$  and their uncertainties are given in Table 21.

# 8 Background Prediction

Here we give the details of how we arrive at the background prediction in a given signal region. We concentrate on the method used to arrive at the central value of the background prediction. The systematic uncertainties will be discussed in Section 9. The actual results for the BG prediction will be given in Section 10.

As mentioned in Section 2, we normalize the main  $t\bar{t}$  background to the  $M_T$  peak. This is actually a bit tricky because we want to minimize the effect of the isolated track veto on lepton + jets events, which may not be terribly well reproduced. Thus, we define two normalization region in the  $M_T$  peak (50 <  $M_T$  < 80 GeV), one before and one after the application of the isolated track veto.

The event counts in pre-veto and post-veto normalization regions are given in Tables 22 and 23. The data-MC agreement in these two tables is quite good, and this is certainly a good thing.

Table 23: MC and data yields in  $M_{\rm T}$  peak region after full selection. The n-jets k-factors have been applied to the  ${\rm t\bar{t}} \to \ell\ell$ . The uncertainties are statistical only. These MC and data yields are used to derive data/MC SFs, the post-veto  $M_{\rm T}$ -SFs, shown in Table 24.

The dominant dilepton background is normalized to the pre-veto normalization region. A pre-veto scale factor  $(SF_{pre})$  is defined as a common scale factors that needs to be applied to the  $t\bar{t}$ , single-top, and W+ jets MC to make the data yield in the pre-veto normalization agree with the MC prediction (the small rare MC component is held fixed). Then, the dilepton background prediction is obtained by multiplying the dilepton BG Monte Carlo by  $SF_{pre}$ .

The  $t\bar{t}$  lepton + jet BG is normalized to post-veto normalization region. A post-veto scale factor  $(SF_{post})$  is defined in (almost) the same way as the pre-veto scale factor. The difference here is that this scale factor applies only to the lepton + jets components and not the dilepton component, since that component is already rescaled by  $SF_{pre}$ . This procedure minimizes the reliance on the understanding of the isolated track veto.

The pre-veto and post-veto SF are shown in Table 24.

Sample	SRA	SRB	SRC	SRD	SRE	SRF	SRG

Table 24:  $M_{\rm T}$  peak Data/MC scale factors. The pre-veto SFs are applied to the  ${\rm t\bar{t}} \to \ell\ell$  sample, while the post-veto SFs are applied to the single lepton samples. The veto SF is shown for comparison across channels. The raw MC is used for backgrounds from rare processes. The uncertainties are statistical only.

- Then the  $t\bar{t}$  lepton + jet BG is obtained by taking the number of MC-predicted  $t\bar{t}$  lepton + jets in the post-veto normalization region, scaling it by  $SF_{post}$ , and multiplying it by the corrected tail-to-peak ratio  $R_{top}$  of Table 21.
- The single top background is obtained in exactly the same way as the  $t\bar{t}$  lepton + jet BG, using the same tail-to-peak ratio. The W+jets background is done in a similar way, but using a different tail-to-peak ratio ( $R_{wjets}$  of Table 21).
- 452 Other (small) backgrounds are taken straight from Monte Carlo, as described in Section 6.

Table 25: MC yields in  $M_{\rm T}$  tail region after full selection. The n-jets k-factors have been applied to the  ${\rm t\bar{t}} \to \ell\ell$ . The uncertainties are statistical only. Note these values are only used for the rare backgrounds prediction.

# 9 Systematic Uncertainties on the Background

453

454

456

457

458

493

In this Section we discuss the systematic uncertainty on the BG prediction. This prediction is assembled from the event counts in the peak region of the transverse mass distribution as well as Monte Carlo with a number of correction factors, as described previously. The final uncertainty on the prediction is built up from the uncertainties in these individual components. The calculation is done for each signal region, for electrons and muons separately.

The choice to normalize to the peak region of  $M_T$  has the advantage that some uncertainties, e.g., lumi-459 nosity, cancel. It does however introduce complications because it couples some of the uncertainties in 460 non-trivial ways. For example, the primary effect of an uncertainty on the rare MC cross-section is to 461 introduce an uncertainty in the rare MC background estimate which comes entirely from MC. But this uncertainty also affects, for example, the  $t\bar{t} \to \text{dilepton BG}$  estimate because it changes the  $t\bar{t}$  normaliza-463 tion to the peak region (because some of the events in the peak region are from rare processes). These effects are carefully accounted for. The contribution to the overall uncertainty from each background 465 source is tabulated in Section 9.9. Here we discuss the uncertainties one-by-one and comment on their impact on the overall result, at least to first order. Second order effects, such as the one described, are 467 also included.

# 9.1 Statistical uncertainties on the event counts in the $M_T$ peak regions

These vary between 2% and 20%, depending on the signal region (different signal regions have different  $E_{\rm T}^{\rm miss}$  requirements, thus they also have different  $M_T$  regions used as control). Since the major backgrounds, eg,  $t\bar{t}$  are normalized to the peak regions, this fractional uncertainty is pretty much carried through all the way to the end. There is also an uncertainty from the finite MC event counts in the  $M_T$  peak regions. This is also included, but it is smaller.

Normalizing to the  $M_T$  peak has the distinct advantages that uncertainties on luminosity, cross-sections, trigger efficiency, lepton ID, cancel out. For the low statistics regions with high  $E_{\rm T}^{\rm miss}$  requirements, the price to pay in terms of event count is that statistical uncertainties start to become significant. In the future we may consider a different normalization startegy in the low statistics regions.

#### 479 9.2 Uncertainty from the choice of $M_T$ peak region

This choice affects the scale factors of Table 24. If the  $M_T$  peak region is not well modelled, this would introduce an uncertainty.

We have tested this possibility by recalculating the post-veto scale factors for a different choice of  $M_T$  peak region (40 <  $M_T$  < 100 GeV instead of the default 50 <  $M_T$  < 80 GeV). This is shown in Table 26.

The two results for the scale factors are very compatible. We do not take any systematic uncertainty for this possible effect.

#### 9.3 Uncertainty on the W+jets cross-section and the rare MC cross-sections

These are taken as 50%, uncorrelated. The primary effect is to introduce a 50% uncertainty on the W+ jets and rare BG background predictions, respectively. However they also have an effect on the other BGs via the  $M_T$  peak normalization in a way that tends to reduce the uncertainty. This is easy to understand: if the W cross-section is increased by 50%, then the W background goes up. But the number of  $M_T$  peak events attributed to  $t\bar{t}$  goes down, and since the  $t\bar{t}$  BG is scaled to the number of  $t\bar{t}$  events in the peak, the  $t\bar{t}$  BG goes down.

#### 9.4 Tail-to-peak ratios for lepton + jets top and W events

The tail-to-peak ratios  $R_{top}$  and  $R_{wjet}$  are described in Section 7. The data/MC scale factors are studied in CR1 and CR2 (Sections 5.1 and 5.2). Only the scale factor for W+jets,  $SFR_{wjet}$ , is used, and its uncertainty is given in Table 13. This uncertainty affects both  $R_{wjet}$  and  $R_{top}$ . The additional systematic uncertainty on  $R_{top}$  from the variation between optimistic and pessimistic scenarios is given in Section 7.

Table 26:  $M_{\rm T}$  peak Data/MC scale factors. The pre-veto SFs are applied to the  ${\rm t\bar{t}} \to \ell\ell$  sample, while the post-veto SFs are applied to the single lepton samples. The veto SF is shown for comparison across channels. The raw MC is used for backgrounds from rare processes. The uncertainties are statistical only.

#### 9.5 Uncertainty on extra jet radiation for dilepton background

As discussed in Section 5.3.1, the jet distribution in  $t\bar{t} \to \text{dilepton MC}$  is rescaled by the factors  $K_3$  and  $K_4$  to make it agree with the data. The 3% uncertainties on  $K_3$  and  $K_4$  comes from data/MC statistics. This results directly in a 3% uncertainty on the dilepton background, which is by far the most important one.

#### 9.6 Uncertainty from MC statistics

507

513

519

520

521

522

523

524

525

This affects mostly the  $t\bar{t} \to \ell\ell$  background estimate, which is taken from Monte Carlo with appropriate correction factors. This uncertainty is negligible in the low  $E_{\rm T}^{\rm miss}$  signal regions, and grows to about 15% in SRG.

# 9.7 Uncertainty on the $t\bar{t} \to \ell\ell$ Background

The  $t\bar{t}$  background prediction is obtained from MC, with corrections derived from control samples in data. The uncertainty associated with the  $t\bar{t}$  background is derived from the level of closure of the background prediction in CR4 (Table 17) and CR5 (Table 19). The results from these control region checks are shown in Figure 15. The uncertainties assigned to the  $t\bar{t} \to \ell\ell$  background prediction based on these tests are 5% (SRA), 10% (SRB), 15% (SRC), 25% (SRD), 40% (SRE-G).

#### 9.7.1 Check of the uncertainty on the $t\bar{t} \to \ell\ell$ Background

We check that the systematic uncertainty assigned to the  $t\bar{t} \to \ell\ell$  background prediction covers the uncertainty associated with the theoretical modeling of the  $t\bar{t}$  production and decay by comparing the background predictions obtained using alternative MC samples. It should be noted that the full analysis is performed with the alternative samples under consideration, including the derivation of the various data-to-MC scale factors. The variations considered are

- Top mass: The alternative values for the top mass differ from the central value by 6 GeV:  $m_{\text{top}} = 178.5 \text{ GeV}$  and  $m_{\text{top}} = 166.5 \text{ GeV}$ .
- Jet-parton matching scale: This corresponds to variations in the scale at which the Matrix Element partons from Madgraph are matched to Parton Shower partons from Pythia. The nominal value is  $x_q > 20$  GeV. The alternative values used are  $x_q > 10$  GeV and  $x_q > 40$  GeV.
- Renormalization and factorization scale: The alternative samples correspond to variations in the scale  $\times 2$  and  $\times 0.5$ . The nominal value for the scale used is  $Q^2 = m_{\text{top}}^2 + \sum_{\text{iets}} p_{\text{T}}^2$ .

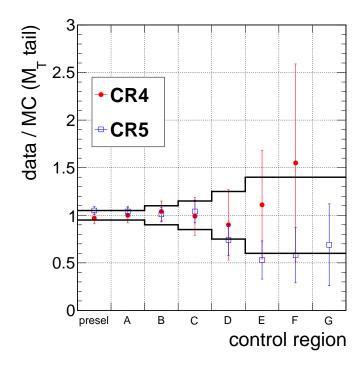

Figure 15: Results of the comparison of yields in the  $M_{\rm T}$  tail comparing the MC prediction (after applying SFs) to data for CR4 and CR5 for all the signal region requirements considered (A-G). The bands indicate the systematic uncertainties assigned based on these tests, ranging from 5% for SRA to 40% for SRE-G.

- Alternative generators: Samples produced with different generators, Powheg (our default) and Madgraph.
- Modeling of taus: The alternative sample does not include Tauola and is otherwise identical to the Powheg sample. This effect was studied earlier using 7 TeV samples and found to be negligible.
- The PDF uncertainty is estimated following the PDF4LHC recommendations. The events are reweighted using alternative PDF sets for CT10 and MSTW2008 and the uncertainties for each are derived using the alternative eigenvector variations and the "master equation". The NNPDF2.1 set with 100 replicas is also used. The central value is determined from the mean and the uncertainty is derived from the  $1\sigma$  range. The overall uncertainty is derived from the envelope of the alternative predictions and their uncertainties. This effect was studied earlier using 7 TeV samples and found to be negligible.

$\Delta/N$ [%]	Madgraph	Mass Up	Mass Down	Scale Up	Scale Down	Match Up	Match Down
SRA	2	2	5	12	7	0	2
SRB	6	0	6	5	12	5	6

Table 27: Relative difference in  $t\bar{t} \to \ell\ell$  predictions for alternative MC samples in the higher statistics regions SRA and SRB. These differences are based on the central values of the predictions. For a fuller picture of the situation, including statistical uncertainties, see Fig. 16.

In Fig. 16 we compare the alternate MC  $t\bar{t} \to \ell\ell$  background predictions for regions A through E. We can make the following observations based on this Figure.

• In the tighter signal regions we are running out of statistics.

• Within the limited statistics, there is no evidence that the situation changes as we go from signal region A to signal region E.

• In signal regions B and above, the uncertainties assigned in Section 9.7 fully cover the alternative MC variations.

542

543

544 545

546

• In order to fully (as opposed as  $1\sigma$ ) cover the alternative MC variations in region A we would have to take a systematic uncertainty of  $\approx 10\%$  instead of 5%. This would be driven by the scale up/scale down variations, see Table 27.

Sample	К3	K4
Powheg	$1.01 \pm 0.03$	$0.93 \pm 0.04$
Madgraph	$1.01 \pm 0.04$	$0.92 \pm 0.04$
Mass Up	$1.00 \pm 0.04$	$0.92 \pm 0.04$
Mass Down	$1.06 \pm 0.04$	$0.99 \pm 0.05$
Scale Up	$1.14 \pm 0.04$	$1.23 \pm 0.06$
Scale Down	$0.89 \pm 0.03$	$0.74 \pm 0.03$
Match Up	$1.02 \pm 0.04$	$0.97 \pm 0.04$
Match Down	$1.02 \pm 0.04$	$0.91 \pm 0.04$

Table 28:  $E_{\rm T}^{\rm miss} > 100$  GeV: Data/MC scale factors used to account for differences in the fraction of events with additional hard jets from radiation in  $t\bar{t} \to \ell\ell$  events.

However, we have two pieces of information indicating that the scale up/scale down variations are inconsistent with the data. These are described below.

The first piece of information is that the jet multiplicity in the scale up/scale down sample is the most inconsistent with the data. This is shown in Table 28, where we tabulate the  $K_3$  and  $K_4$  factors of Section 5.3.1 for different tt MC samples. The data/MC disagreement in the  $N_{jets}$  distribution for the scale up/scale down samples is also shown in Fig. 17 and 18. This should be compared with the equivalent  $N_{jets}$  plots for the default Powheg MC, see Fig. 9, which agrees much better with data.

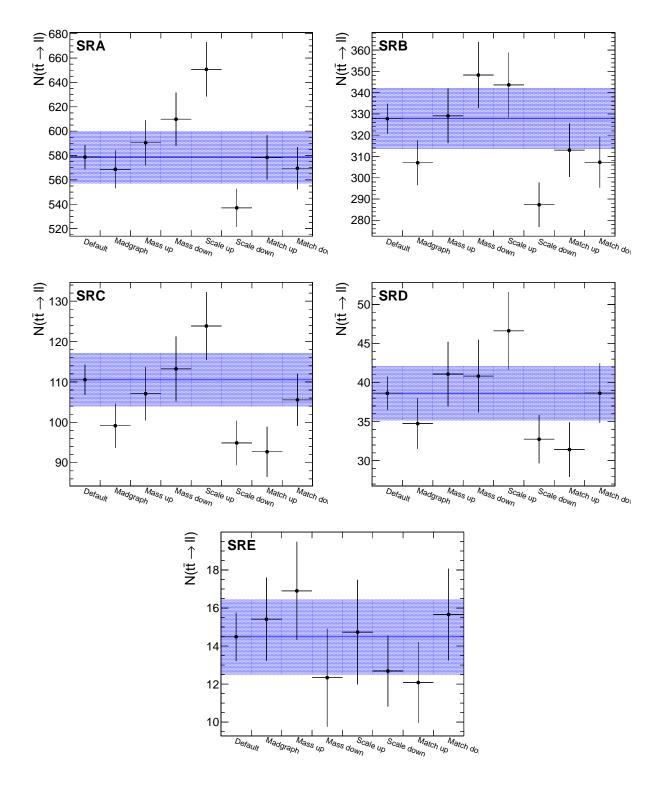

Figure 16: Comparison of the  $t\bar{t} \to \ell\ell$  central prediction with those using alternative MC samples. The blue band corresponds to the total statistical error for all data and MC samples. The alternative sample predictions are indicated by the datapoints. The uncertainties on the alternative predictions correspond to the uncorrelated statistical uncertainty from the size of the alternative sample only. Note the suppressed vertical scales.

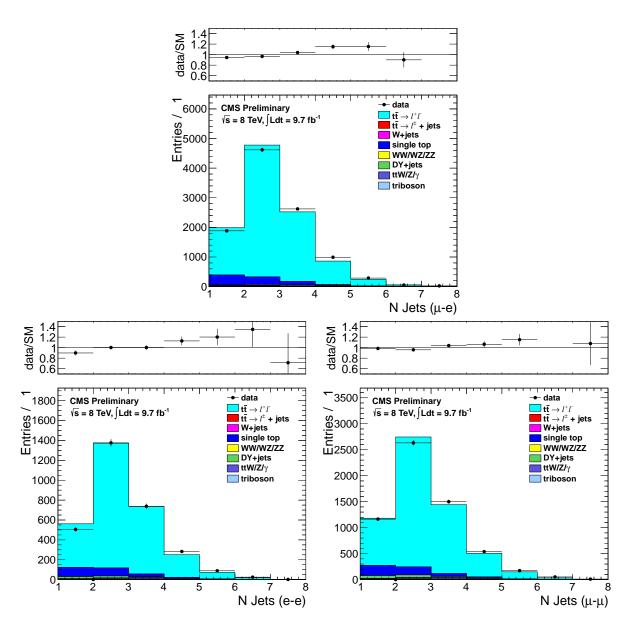

Figure 17: SCALE UP: Comparison of the jet multiplicity distribution in data and MC for dilepton events in the e- $\mu$  (top), e-e (bottom left) and  $\mu$ - $\mu$  (bottom right) channels.

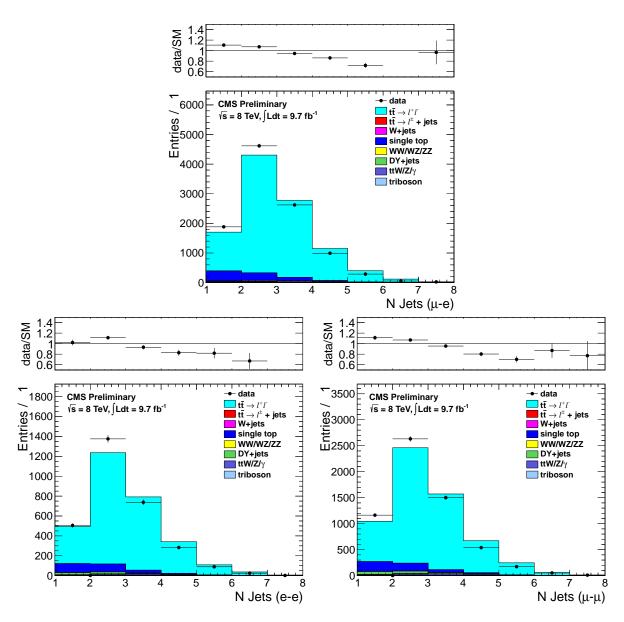

Figure 18: SCALE DOWN: Comparison of the jet multiplicity distribution in data and MC for dilepton events in the e- $\mu$  (top), e-e (bottom left) and  $\mu$ - $\mu$  (bottom right) channels.

The second piece of information is that we have performed closure tests in CR5 using the alternative MC samples. These are exactly the same tests as the one performed in Section 5.4 on the Powheg sample. As we argued previously, this is a very powerful test of the background calculation. The results of this test are summarized in Table 29. Concentrating on the relatively high statistics CR5A region, we see for all  $t\bar{t}$  MC samples except scale up/scale down we obtain closure within  $1\sigma$ . The scale up/scale down tests closes worse, only within  $2\sigma$ . This again is evidence that the scale up/scale down variations are in disagreement with the data.

Table 29: Ratio of yields in  $M_{\rm T}$  tail comparing the MC prediction (after applying SFs) to data. The uncertainties are statistical only.

Based on the two observations above, we argue that the MC scale up/scale down variations are too extreme. We feel that a reasonable choice would be to take one-half of the scale up/scale down variations in our MC. This factor of 1/2 would then bring the discrepancy in the closure test of Table 29 for the scale up/scale down variations from about  $2\sigma$  to about  $1\sigma$ .

Then, going back to Table 27, and reducing the scale up/scale down variations by a factor 2, we can see that a systematic uncertainty of 5% covers the range of reasonable variations from different MC models in SRA and SRB. Note that this 5% is also consistent with the level at which we are able to test the closure of the method with alternative samples in CR5 for the high statistics regions (Table 29). The range of reasonable variations obtained with the alternative samples are consistent with the uncertainties assigned for the  $t\bar{t} \to \ell\ell$  background based on the closure of the background predictions and data in CR4 and CR5.

#### 9.8 Uncertainty from the isolated track veto

This is the uncertainty associated with how well the isolated track veto performance is modeled by the Monte Carlo. This uncertainty only applies to the fraction of dilepton BG events that have a second  $e/\mu$  or a one prong  $\tau \to h$ , with  $P_T > 10$  GeV in  $|\eta| < 2.4$ . This fraction is about 1/3, see Table 30. The uncertainty for these events is 6% and is obtained from tag-and-probe studies, see Section 9.8.1.

Sample	SRA	SRB	SRC	SRD	SRE	SRF	SRG
$\mu$ Frac. $t\bar{t} \to \ell\ell$ with true iso. trk.	$0.32 \pm 0.03$	$0.30 \pm 0.03$	$0.32 \pm 0.06$	$0.34 \pm 0.10$	$0.35 \pm 0.16$	$0.40 \pm 0.24$	$0.50 \pm 0.32$
e Frac. $t\bar{t} \to \ell\ell$ with true iso. trk.	$0.32 \pm 0.03$	$0.31 \pm 0.04$	$0.33 \pm 0.06$	$0.38 \pm 0.11$	$0.38 \pm 0.19$	$0.60 \pm 0.31$	$0.61 \pm 0.45$

Table 30: Fraction of  $t\bar{t} \to \ell\ell$  events with a true isolated track.

#### 9.8.1 Isolated Track Veto: Tag and Probe Studies

In this section we compare the performance of the isolated track veto in data and MC using tag-and-probe studies with samples of  $Z\rightarrow ee$  and  $Z\rightarrow \mu\mu$ . The purpose of these studies is to demonstrate that the efficiency to satisfy the isolated track veto requirements is well-reproduced in the MC, since if this were not the case we would need to apply a data-to-MC scale factor in order to correctly predict the  $t\bar{t}\rightarrow\ell\ell$  background.

This study addresses possible data vs. MC discrepancies for the **efficiency** to identify (and reject) events with a second **genuine** lepton (e,  $\mu$ , or  $\tau \to 1$ -prong). It does not address possible data vs. MC discrepancies in the fake rate for rejecting events without a second genuine lepton; this is handled separately in the top normalization procedure by scaling the  $t\bar{t} \to \ell + jets$  contribution to match the data in the  $M_T$  peak after applying the isolated track veto.

Furthermore, we test the data and MC isolated track veto efficiencies for electrons and muons since we are using a Z tag-and-probe technique, but we do not directly test the performance for hadronic tracks from  $\tau$  decays. The performance for hadronic  $\tau$  decay products may differ from that of electrons and muons for two reasons. First, the  $\tau$  may decay to a hadronic track plus one or two  $\pi^0$ 's, which may decay to  $\gamma\gamma$  followed by a photon conversion. As shown in Figure 29, the isolation distribution for charged tracks from  $\tau$  decays that are not produced in association with  $\pi^0$ s are consistent with that from es and  $\mu$ s. Since events from single prong  $\tau$  decays produced in association with  $\pi^0$ s comprise a small fraction of the total sample, and since the kinematics of  $\tau$ ,  $\pi^0$  and  $\gamma \to e^+e^-$  decays are well-understood, we currently demonstrate that the isolation is well-reproduced for electrons and muons only. Second, hadronic tracks may undergo nuclear interactions and hence their tracks may not be reconstructed. As discussed above, independent studies show that the MC reproduces the hadronic tracking efficiency within 4%, leading to a total background uncertainty of less than 0.5% (after taking into account the fraction of the total background due to hadronic  $\tau$  decays with  $p_T > 10$  GeV tracks), and we hence regard this effect as negligible.

The tag-and-probe studies are performed in the full data sample, and compared with the DYJets madgraph sample. All events must contain a tag-probe pair (details below) with opposite-sign and satisfying the Z mass requirement 76–106 GeV. We compare the distributions of absolute track isolation for probe electrons/muons in data vs. MC. The contributions to this isolation sum are from ambient energy in the event from underlying event, pile-up and jet activitiy, and hence do not depend on the  $p_{\rm T}$  of the probe lepton. We therefore restrict the probe  $p_{\rm T}$  to be > 30 GeV in order to suppress fake backgrounds with steeply-falling  $p_{\rm T}$  spectra. To suppress non-Z backgrounds (in particular  ${\rm t\bar{t}}$ ) we require  $E_{\rm T}^{\rm miss}$  < 30 GeV and 0 b-tagged events. The specific criteria for tags and probes for electrons and muons are:

#### Electrons

- Tag criteria
  - \* Electron passes full analysis ID/iso selection
- \*  $p_{\rm T} > 30 \; {\rm GeV}, \, |\eta| < 2.1$ 
  - \* Matched to the single electron trigger HLT Ele27 WP80 v\*
  - Probe criteria

```
* Electron passes full analysis ID selection
616
                    * p_{\rm T} > 30 \; {\rm GeV}

The absolute track isolation distributions for passing probes are displayed in Fig. 19. In general we observe good agreement between data and MC. To be more quantitative, we compare the data vs. MC efficiencies to satisfy absolute track isolation requirements varying from > 1 GeV to > 5 GeV, as summarized in Table 31. In the  $\ge 0$  and  $\ge 1$  jet bins where the efficiencies can be tested with statistical precision, the data and MC efficiencies agree within 6%, and we apply this as a systematic uncertainty on the isolated track veto efficiency. For the higher jet multiplicity bins the statistical precision decreases, but we do not observe any evidence for a data vs. MC discrepancy in the isolated track veto efficiency.

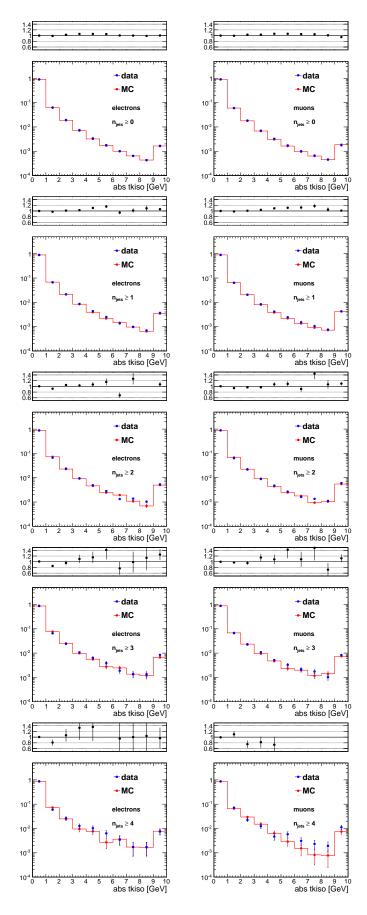

Figure 19: Comparison of the absolute track isolation in data vs. MC for electrons (left) and muons (right) for events with the  $N_{\rm jets}$  requirement varied from  $N_{\rm jets} \geq 0$  to  $N_{\rm jets} \geq 4$ .

Table 31: Comparison of the data vs. MC efficiencies to satisfy the indicated requirements on the absolute track isolation, and the ratio of these two efficiencies. Results are indicated separately for electrons and muons and for various jet multiplicity requirements.

### 9.9 Summary of uncertainties

636

638

The contribution from each source to the total uncertainty on the background yield is given in Tables 32 and 33 for the relative and absolute uncertainties, respectively. In the low- $E_{\rm T}^{\rm miss}$  regions the dominant uncertainty comes from the top tail-to-peak ratio,  $R_{top}$  (Section 7), while in the high- $E_{\rm T}^{\rm miss}$  regions the t $\bar{t} \to \ell \ell$  systematic uncertainty dominates (Section 9.7).

Sample	SRA	SRB	SRC	SRD	SRE	SRF	SRG

### 10 Results

The results of the search are shown in Table 34, including both statistical and systematic uncertainties. Agreement is observed between the data and the predicted background for all signal regions. The predicted and observed  $E_{\rm T}^{\rm miss}$  distribution for  $E_{\rm T}^{\rm miss} > 150$  GeV and  $M_{\rm T} > 120$  GeV are shown in Figure 20, obtained from the yields for SRB to SRG. Two signal points are shown for comparison, corresponding to the low and high stop mass sensitivity boundaries for this search. This shows that the lower  $E_{\rm T}^{\rm miss}$  region is more sensitive to lighter stop signals, while the higher  $E_{\rm T}^{\rm miss}$  region is more sensitive to heavier stops, for the T2tt signal model shown. The  $M_T$  distributions for increasing values of  $E_{\rm T}^{\rm miss}$  are shown in Fig 21 and 22.

Table 34: The result of the search.

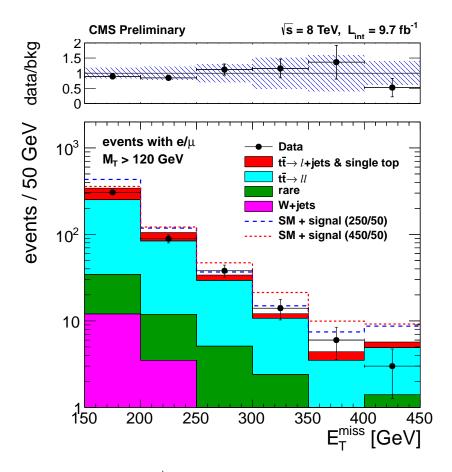

Figure 20: Predicted and observed  $E_{\rm T}^{\rm miss}$  for  $M_{\rm T}>120$  GeV, obtained from the yields for SRB to SRG. Note SRB corresponds to the integral of the distribution, while subsequent signal regions SRC to SRG correspond to integrals from subsequent bins. The band on the ratio (above) corresponds to the full relative background uncertainty.

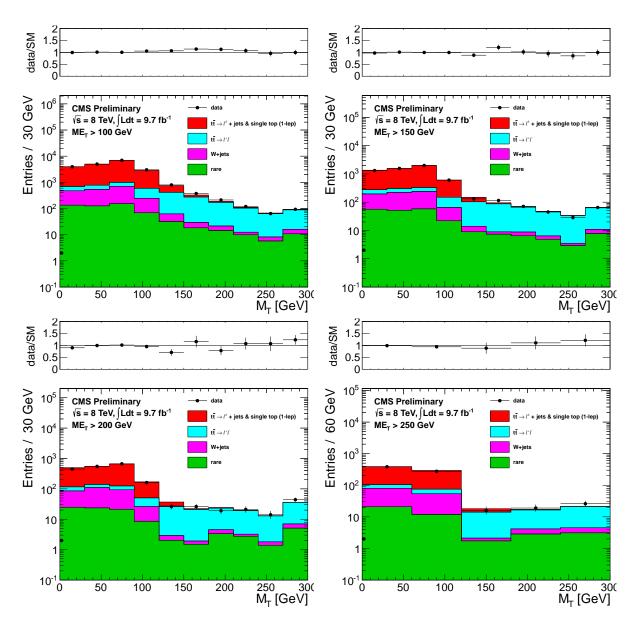

Figure 21:  $M_T$  in the data compared to SM Monte Carlo, for increasing values of  $E_{\rm T}^{\rm miss}$ . Only statistical uncertainties are shown. Note that the MC tails have not been rescaled at this point.

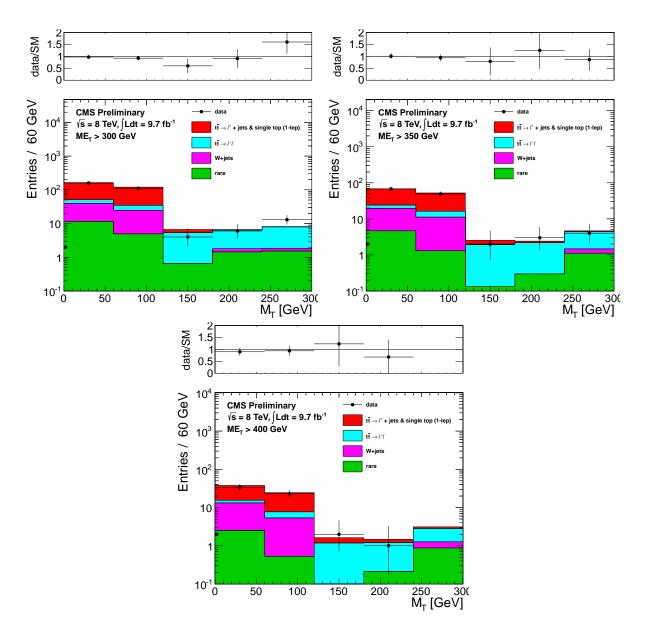

Figure 22:  $M_T$  in the data compared to SM Monte Carlo, for increasing values of  $E_{\rm T}^{\rm miss}$ . Only statistical uncertainties are shown. Note that the MC tails have not been rescaled at this point.

### 649 11 Limits

In this Section, we interpret the results of this search in terms of the T2tt and T2bw simplified models, see Figure 23. Note T2tt is included at the moment, T2bw is to be added. The branching fractions for the stop decay are assumed to be 100% for each model. The signal samples are normalized to cross sections calculated at NLO in  $\alpha_S$ , including the resummation of soft gluon emission at next-to-leading-logarithmic accuracy (NLO+NLL).

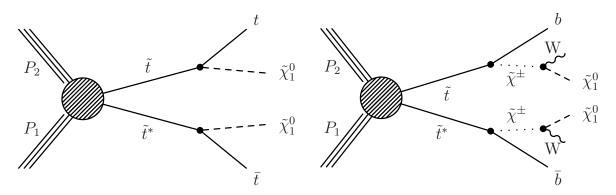

Figure 23: Diagram for the T2tt (left) and T2bw (right) simplified models.

The exclusion is performed using the results from the counting experiments in the signal regions defined by  $E_{\rm T}^{\rm miss}$  and  $M_{\rm T}$  and listed in Table 4. The cross section upper limit calculation is performed with the LandS software using the LHC-type CLs criterion.

The signal efciency uncertainties include the luminosity (4.4%), lepton ID and isolation efciency (2%), and trigger efciency (3%). The uncertainty from JES is assessed for each scan point following the POG-recommended procedure, by varying the jet energies by the  $p_{\rm T}$ - and  $\eta$ - dependent uncertainties, and propagating this to the jet multiplicity,  $E_{\rm T}^{\rm miss}$  and  $M_{\rm T}$ . The official b-tagging scale-factors for CSVM are used to compute scale factors for the signal. The results are nearly constant across the model parameter space, and an overall scale factor of  $(98 \pm 2)\%$  is used.

The signal efficiency in the stop vs LSP mass plane for T2tt is shown for each signal region in Figures 24, 25 and 26 (left). These distributions show how challenging it is to have sensitivity near the kinematical boundaries. The cross section upper limits, along with the observed and expected exclusion contours, are also shown in Figures 24, 25 and 26 (right). The complementarity of the different signal regions is readily apparent. The sensitivity to low (high) stop masses comes from the low (high)  $E_{\rm T}^{\rm miss}$  signal regions.

A combined result is obtained using the observed limit from the signal region with the best expected limit for each scan point. The combined cross section upper limits, with the observed and expected exclusion contours, are shown in Figure 27 (left). The signal region with the best expected limit for each scan point is also shown in Figure 27 (right). This search probes stops in the T2tt scenario with masses in the range 250 GeV to 450 GeV for LSP masses up to about 110 GeV.

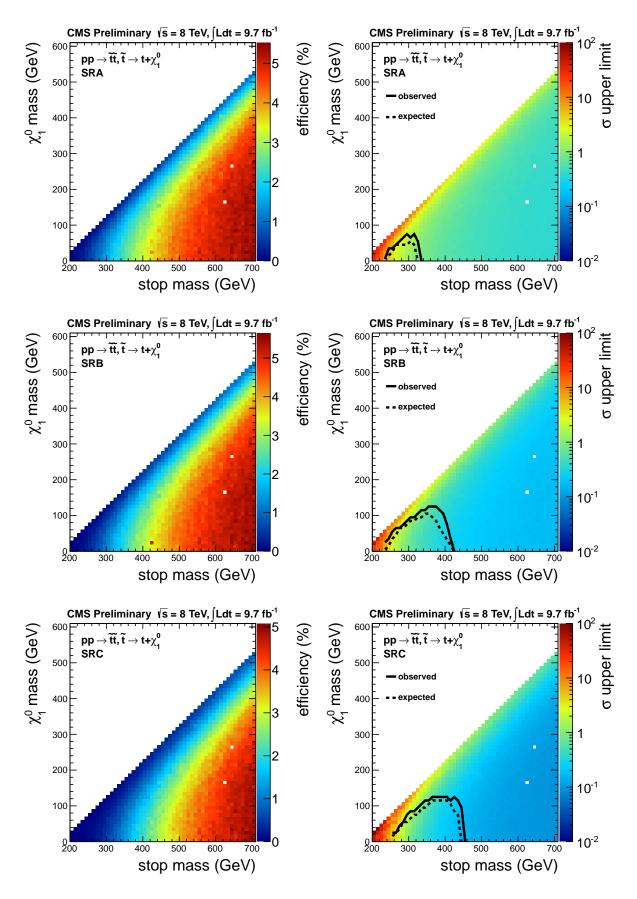

Figure 24: Signal efficiency (left) and cross section upper limit (right) for the T2tt model, showing both the expected and observed exclusion contours. The results for signal regions SRA (top), SRB (middle) and SRC (bottom) are shown separately.

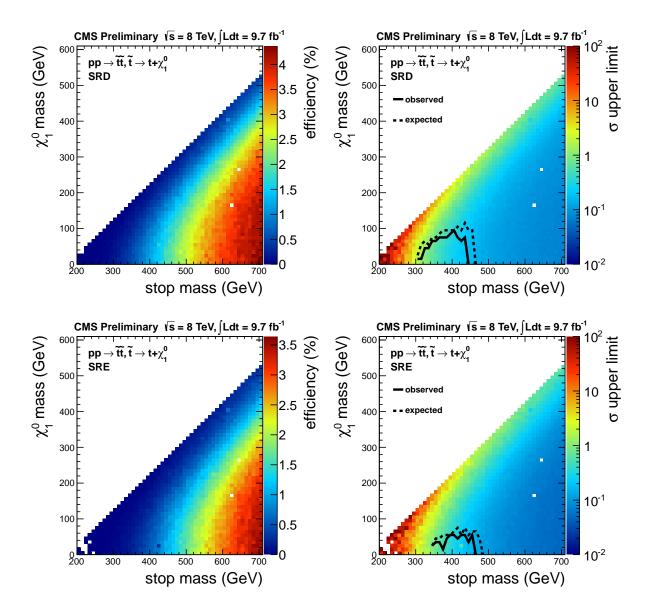

Figure 25: Signal efficiency (left) and cross section upper limit (right) for the T2tt model, showing both the expected and observed exclusion contours. The results for signal regions SRD (top), and SRE (bottom) are shown separately.

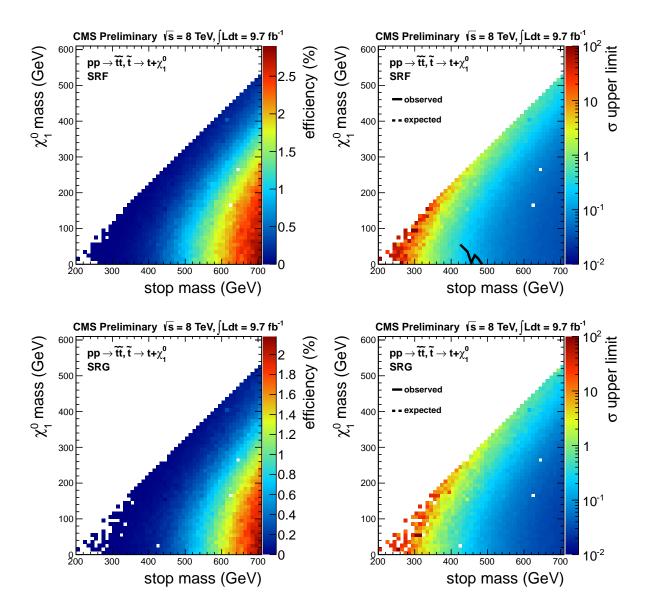

Figure 26: Signal efficiency (left) and cross section upper limit (right) for the T2tt model, showing both the expected and observed exclusion contours. The results for signal regions SRF (top), and SRG (bottom) are shown separately.

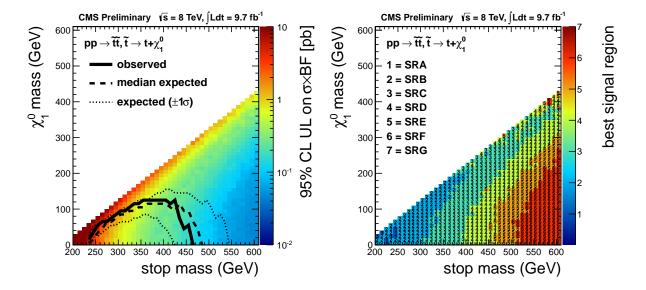

Figure 27: Upper limit on the cross section for the T2tt model in the plane of stop vs. LSP mass, showing both the expected (dashed) and observed (solid curve) exclusion contours (left). The observed limit is selected from the signal region with the best expected limit (shown on right). All uncertainties are included and the dotted contours around the dashed expected limit correspond to the  $\pm 1\sigma$  result.

# 674 12 Conclusion

This note presents a search for the production of stop quark pairs in events with a single isolated lepton, several jets, missing transverse energy, and large transverse mass. The dataset used corresponds to an integrated luminosity of  $9.7 \, \text{fb}^{-1}$  at center-of-mass energy of 8 TeV. Seven signal regions are defined, based on  $E_{\text{T}}^{\text{miss}}$  and  $M_{\text{T}}$  requirements. Agreement is observed between the data and the predicted backgrounds for all signal regions. The results are interpreted in the context of simplified SUSY models where the stops decay to top-neutralino or b-chargino and are used to place constraints on the stop mass.

# A Performance of the Isolation Requirement

The last requirement used in the analysis is an isolated track veto. This selection criteria rejects events containing a track of  $p_{\rm T} > 10$  GeV with relative track isolation  $\sum p_{\rm T}/p_{\rm T}(trk)$  in a cone of size R = 0.3 < 0.1. It may be noted that only tracks consistent with the vertex with highest  $\sum p_{\rm T}^2$  are considered in order to reduce the impact of spurious tracks, for example from pileup interactions. This requirement has very good performance. Figure 28 shows the efficiency for rejecting dilepton events compared to the efficiency for selecting single lepton events for various cone sizes and cut values. The chosen working point provides a signal efficiency of  $\epsilon(sig) = 92\%$  for a background rejection of  $\epsilon(bkg) = 53\%$  in MC. With "signal" ("background") we are referring to  $t\bar{t} \to \ell + {\rm jets}~(t\bar{t} \to \ell\ell)$ .

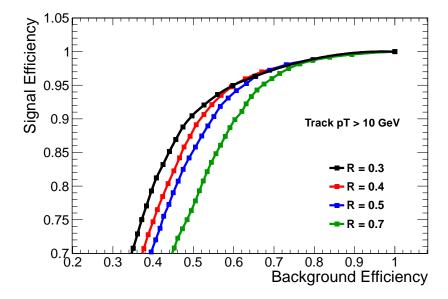

Figure 28: Comparison of the performance in terms of signal (single lepton events) efficiency and background (dilepton events) rejection for various cone sizes and cut values. The current isolation requirement uses a cone of size  $\Delta R = 0.3$  and a cut value of 0.1, corresponding to  $\epsilon(siq) = 92\%$  for  $\epsilon(bkq) = 53\%$ .

It should be emphasized that the isolated track veto has a different impact on the samples with a single lepton (mainly  $t\bar{t} \to \ell + jets$  and W+jets) and that with two leptons (mainly  $t\bar{t} \to \ell \ell$ ). For the dilepton background, the veto rejects events which have a genuine second lepton. Thus the performance may be understood as an efficiency  $\epsilon_{iso\ trk}$  to identify the isolated track. In the case of the single lepton background, the veto rejects events which do not have a genuine second lepton, but rather which contain a "fake" isolated track. The isolated track veto thus effectively scales the single lepton sample by (1- $\epsilon_{fake}$ ), where  $\epsilon_{fake}$  is the probability to identify an isolated track with  $p_T > 10$  GeV in events which contain no genuine second lepton. It is thus necessary to study the isolated track efficiency  $\epsilon(trk)$  and  $\epsilon_{fake}$  in order to fully characterize the veto performance.

The veto efficiency for dilepton events is calculated using the tag and probe method in Z events. A good lepton satisfying the full ID and isolation criteria and matched to a trigger object serves as the tag. The probe is defined as a track with  $p_{\rm T} > 10$  GeV that has opposite charge to the tag and has an invariant mass with the probe consistent with the Z mass.

The variable used to study the performance of the veto is the absolute track isolation, since it removes the dependence of the isolation variable on the  $p_{\rm T}$  of the object under consideration. This is particularly

useful because the underlying  $p_T$  distribution is different for second leptons in  $t\bar{t} \to \ell\ell$  events compared to Z events, particularly due to the presence of  $\tau$ s that have softer decay products. As shown in Figure 29, the absolute isolation is consistent between Z+4 jet events and  $t\bar{t} \to \ell\ell$  events, including leptons from W and  $\tau$  decays. This supports the notion that the isolation, defined as the energy surrounding the object under consideration, depends only on the environment of the object and not on the object itself. The isolation is thus sensitive to the ambient pileup and jet activity in the event, which is uncorrelated with the lepton  $p_T$ . It is thus justified to use tag and probe in Z+4 jet events, where the jet activity is similar to  $t\bar{t} \to \ell\ell$  events in our  $N_{\rm jets} > 4$  signal region, in order to estimate the performance of the isolation requirement for the various leptonic categories of  $t\bar{t} \to \ell\ell$  events.

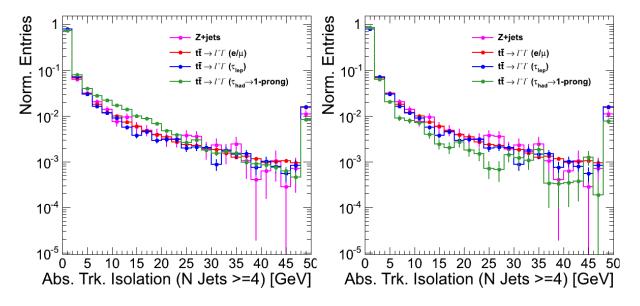

Figure 29: Comparison of absolute track isolation for track probes in Z + 4 jet and  $t\bar{t} \to \ell\ell$  events for different lepton types. The isolation variables agree across samples, except for single prong  $\tau$ s, that tend to be slightly less isolated (left). The agreement across isolation distributions is recovered after removing single prong  $\tau$  events produced in association with  $\pi^0$ s from the sample (right).

The calculation of the background prediction is a bit complicated. Here we walk the reader through a concrete example.

NB: the numbers in this section corresponded to the numbers in V3 of the analysis note.
They will not be updated, because this is meant as an illustration only.

The main background is  $t\bar{t}$ . The main idea is to normalize to the  $M_T$  peak region (50 <  $M_T$  < 80 GeV). This eliminates dependence on  $t\bar{t}$  cross-section, luminosity, trigger efficiency, JES, lepton ID, etc. This gets a bit complicated because the  $M_T$  peak region, while dominantly  $t\bar{t}$  lepton + jets, also includes some W+jets,  $t\bar{t} \to \ell\ell$ , rare processes, etc. Also, we want to minimize our need to understand the effect of the isolated track veto on  $t\bar{t} \to \ell + j$ ets. As a result we actually define two  $M_T$  peak regions: one before and one after applying the isolated track veto. Then the  $t\bar{t} \to \ell \ell$  background is normalized the the "before veto" region, and the  $t\bar{t} \to \ell + j$ ets and W+jets background are normalized to the "post veto" region.

This complex procedure is important for the high statistics signal regions with relatively low  $E_{\rm T}^{\rm miss}$  requirements, eg, SRA. For these SRs we want to keep the systematics low in order to be sensitive to low mass stop; for the signal regions with hard cuts on  $E_{\rm T}^{\rm miss}$  this is less important. However, we apply the same procedure to all SRs.

For concreteness, we show the calculation for SRA, electron channel. The MC and data event counts used in the background calculation are collected in Table 35. Note that the background uncertainties have already been described in Section 9. The one tricky point to keep in mind is that when the W+jets and rare cross-sections are changed by their assumed uncertainties (50% each), the whole calculation describe below is repeated in order to take care of all the correlations properly.

Sample	$M_T$ peak, before trk veto	$M_T$ peak, after trk veto	Signal Region A
$t\bar{t} \to \ell\ell$	$290 \pm 6$	$116 \pm 4$	$261 \pm 6$
$t\bar{t} \to \ell + jets (1\ell)$	$2899 \pm 19$	$2595 \pm 18$	not used
W+jets	$252 \pm 28$	$236 \pm 28$	not used
Rare	$89 \pm 5$	$62 \pm 4$	$26 \pm 2$
Total	$3530 \pm 35$	$3009 \pm 34$	not used
Data	3358	2787	not used

Table 35: Data and MC event counts used to predict the background in SRA, for electron events. Uncertainties are statistical only. The trigger efficiency has been applied to the MC samples. In the case of  $t\bar{t} \to \ell\ell$  the  $K_3$  and  $K_4$  factors of Section 5.3.1 have also been applied.

#### 739 B.1 Central value of dilepton background

A "before veto" scale factor is defined from the second column in Table 35 as the factor by which all MC except the "rare" need to be scaled up in order to have data/MC agreement. This is

$$SF_{pre} = (3358 - 89)/(2899 + 252 + 290) = 0.950.$$

Then the  $t\bar{t} \to \ell\ell$  background prediction is the number of events predicted by the MC in SRA (261 from the last column of SRA), rescaled by  $SF_{pre}$ . The result for the central value is 248 events.

## $_{5}$ B.2 Central value of the ${ m tar t} o \ell + { m jets}$ background

A "post veto" scale factor is defined from the third column in Table 35 as the factor by which the  $t\bar{t} \to \ell + jets$  and the W+jets backgrounds need to be scaled to have data/MC agreement.

$$SF_{post} = (2787 - 62 - SF_{pre} \cdot 116)/(2595 + 236) = 0.924.$$

Then the  $t\bar{t} \to \ell + {
m jets}$  background is obtained as the product of the following three factors

- $SF_{post} = 0.924$  as obtained above
- 2595, from the third column of Table 35

- The tail-to-peak ratio  $R_{top}=0.045$  from Table 21
- The result for the central value is 108 events.

# B.3 Central value for the $W+{f j}$ ets background

- T55 It is calculated as the product of
- $SF_{post} = 0.924$  from Section B.2
- 236, from the third column of Table 35
- The tail-to-peak ratio  $R_{wjet} = 0.066$  from Table 21
- The result for the central value is 14.3 events.

### B.4 Central value for the rare backgrounds

761 This is 26 events from Table 35

# C Additional CR Data and MC Comparisons

This appendix shows some additional comparisons of the data and MC background samples for various CRs. Figure 30 shows some additional components of the  $M_{\rm T}$ , the lepton  $p_{\rm T}$  and the azimuthal angle between the lepton and the  $E_{\rm T}^{\rm miss}$  for CR1 (Section 5.1). Figure 31 shows the equivalent distributions for CR2 (Section 5.2), the positive lepton  $p_{\rm T}$  and the angle between this lepton and the pseudo- $E_{\rm T}^{\rm miss}$ . Similarly, figure 34 shows the lepton  $p_{\rm T}$  and and the azimuthal angle between the lepton and the  $E_{\rm T}^{\rm miss}$  for CR5 (Section 5.4). Figures 32 and 33 provide some data and MC comparisons of the  ${\rm t\bar{t}} \to \ell\ell$  control sample CR4 (Section 5.3) for various kinematic distributions: leading lepton  $p_{\rm T}$  and eta, as well as the angles between the two leptons and between the leading lepton and the  $E_{\rm T}^{\rm miss}$ . These distributions show quite good agreement between data and MC. More quantitative information is included in the section discussing each control region.

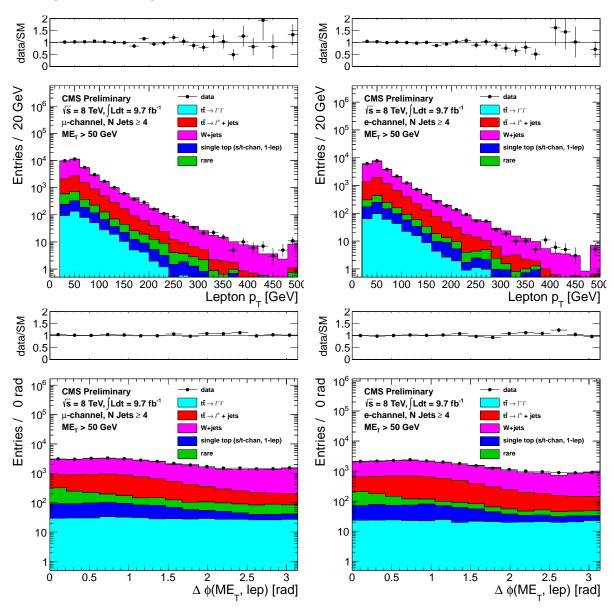

Figure 30: Comparison of the lepton  $p_{\rm T}$  (top) and azimuthal angle between the  $E_{\rm T}^{\rm miss}$  and the lepton (bottom) for data vs. MC for events with a leading muon (left) and leading electron (right) satisfying the requirements of CR1.

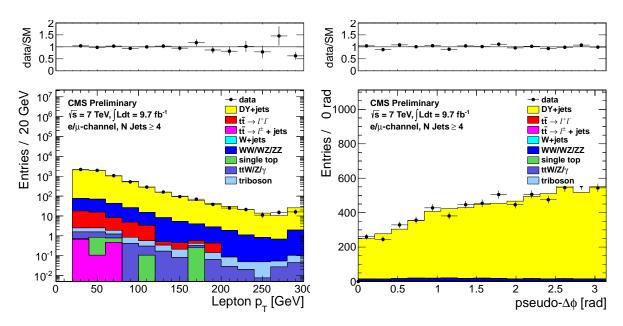

Figure 31: Comparison of the positive lepton  $p_{\rm T}$  (left) and the azimuthal angle between this lepton and the pseudo- $E_{\rm T}^{\rm miss}$  (right) distributions in data vs. MC for events satisfying the requirements of CR2, combining both the muon and electron channels.

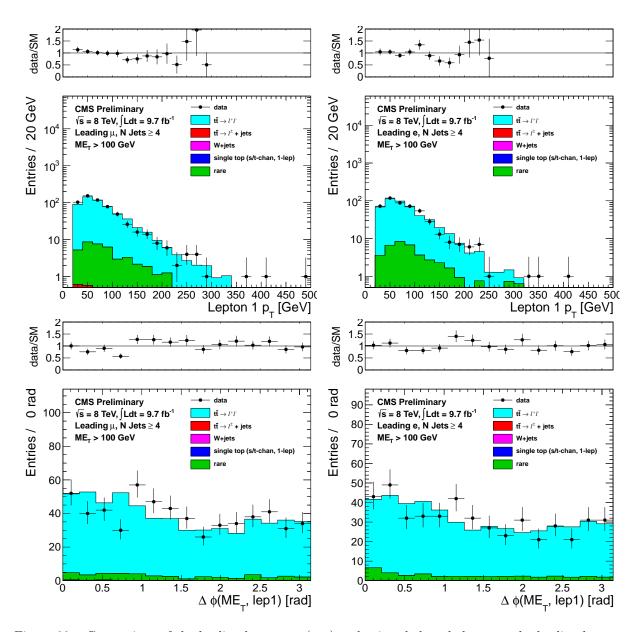

Figure 32: Comparison of the leading lepton  $p_{\rm T}$  (top) and azimuthal angle between the leading lepton and the  $E_{\rm T}^{\rm miss}$  for  $E_{\rm T}^{\rm miss} > 100$  GeV distributions in data vs. MC for events with a leading muon (left) and leading electron (right) satisfying the requirements of CR4.

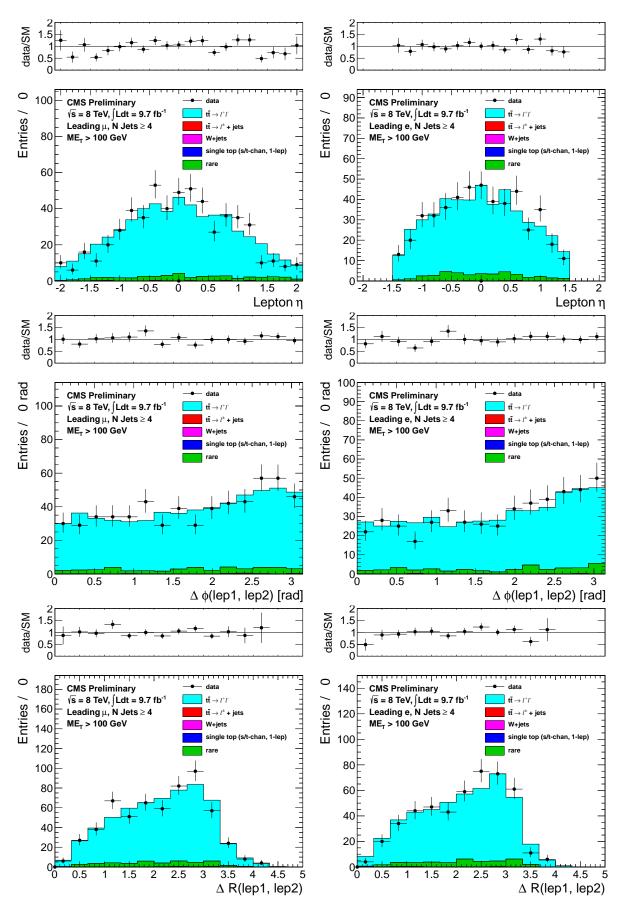

Figure 33: Comparison of the leading lepton eta (top), difference in the azimuthal angle (center) and  $\Delta R$  separation (bottom) between the two leptons for  $E_{\rm T}^{\rm miss} > 100$  GeV distributions in data vs. MC for events with a leading muon (left) and leading electron (right) satisfying the requirements of CR4.

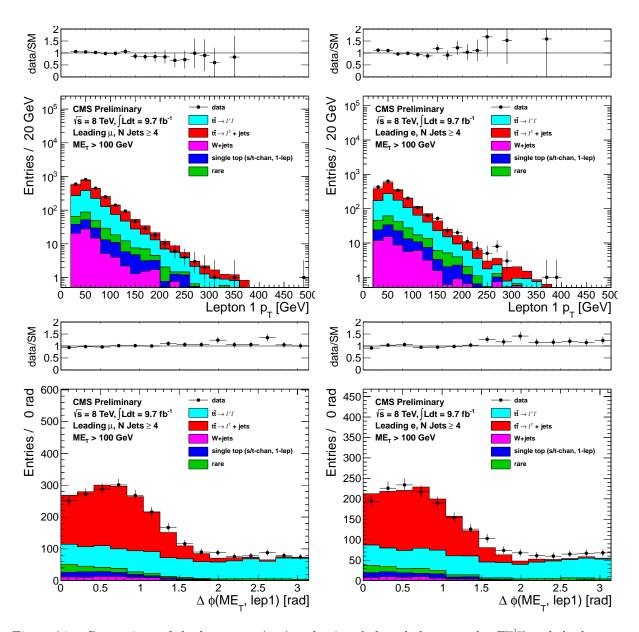

Figure 34: Comparison of the lepton  $p_{\rm T}$  (top) and azimuthal angle between the  $E_{\rm T}^{\rm miss}$  and the lepton (bottom) for data vs. MC for  $E_{\rm T}^{\rm miss} > 100$  GeV for events with a leading muon (left) and leading electron (right) satisfying the requirements of CR5.

# 773 D Glossary of abbreviations

```
R_{wjet}^{MC}, R_{wjet}
774
    Monte Carlo and corrected ratios of W+jets events in the M_T tail to the M_T peak.
    R_{top}^{MC}, R_{top} Monte Carlo and corrected ratios of t\bar{t} or single-top \ell+ jets events in the M_T tail to the M_T peak.
776
    SFR_{wjet} Data/MC scale factor for R_{wjet}^{MC}
778
779
780
     Data/MC scale factor for R_{top}^{MC} (not used)
782
     K_3 and K_4
784
     Scale factors for t\bar{t} \to \ell\ell events with one or two extra jets from radiation
785
     SF_{pre} and SF_{post}
787
    Scale factors to be applied to MC to normalize to the yields in the M_T control region before and after
788
    the application of the isolated track veto.
